To my husband,

Wayne K. Hoy

A remarkable scholar,
A demanding and caring mentor,
A dedicated father and grandfather,
And a wonderful companion in life.

The best is yet to be...

ABOUT THE AUTHOR

So you will know your author a bit better, here is some information.

Anita Woolfolk Hoy was born in Fort Worth, Texas, where her mother taught child development at TCU and her father was an early worker in the computer industry. She is a Texas Longhorn—all her degrees are from the University of Texas, Austin, the last one a PhD. After graduating, she was a psychologist working with children in elementary and secondary schools in 15 counties of central Texas. She began her career in higher education as a professor of educational psychology at Rutgers University, and then moved to The Ohio State University in 1994. Today she is Professor Emerita at Ohio State. Anita's research focuses on motivation and cognition, specifically, students' and teachers' sense of efficacy and teachers' beliefs about education. For many years she was the editor of *Theory Into Practice*, a journal that brings the best ideas from research to practicing educators. With students and colleagues, she has published over 150 books, book chapters, and research articles. Anita has served as Vice-President for Division K (Teaching & Teacher Education) of the American Educational Research Association and President of Division 15 (Educational Psychology) of the American Psychological Association. Before completing this fourteenth edition of *Educational Psychology*, she collaborated with Nancy Perry, University of British Columbia, to write the second edition of *Child Development* (Pearson, 2015), a book for all those who work with and love children.

PREFACE

Many of you reading this book are enrolled in an educational psychology course as part of your professional preparation for teaching, counseling, speech therapy, nursing, or psychology. The material in this text should be of interest to everyone who is concerned about education and learning, from the nursery school volunteer to the instructor in a community program for adults learning English. No background in psychology or education is necessary to understand this material. It is as free of jargon and technical language as possible, and many people have worked to make this edition clear, relevant, and interesting.

Since the first edition of *Educational Psychology* appeared, there have been many exciting developments in the field. The fourteenth edition continues to emphasize the educational implications and applications of research on child development, cognitive science, learning, motivation, teaching, and assessment. Theory and practice are not separated in the text, but are considered together. The book is written to show how information and ideas drawn from research in educational psychology can be applied to solve the everyday problems of teaching. To help you explore the connections between research and practice, you will find in these pages a wealth of examples, lesson segments, case studies, guidelines, and even practical tips from experienced teachers. As you read this book, I believe you will see the immense value and usefulness of educational psychology. The field offers unique and crucial knowledge to any who dare to teach and to all who love to learn.

NEW CONTENT IN THE FOURTEENTH EDITION

Across the book, there is increased coverage of a number of important topics. Some of these include:

- Increased coverage of the **brain, neuroscience, and teaching** emphasized in Chapter 2 and also integrated into several other chapters.
- Increased coverage of **the impact of technology and virtual learning environments** on the lives of students and teachers today.
- Increased emphasis on **diversity in today's classrooms** (see especially Chapters 1 to 6). Portraits of students in educational settings make diversity real and human for readers. In a number of chapters there are new exercises asking readers to "Put Yourself in Their Place" as a way to develop empathy for many students and situations.
- Increased coverage of effective application of learning principles as identified by the *Institute for Educational Sciences* (<https://ies.ed.gov/ncee/wwc/PracticeGuide/1>)

Key content changes in each chapter include:

- **Chapter 1:** My goal is that this text will provide the knowledge and skills that will enable students to build a solid foundation for an authentic sense of teaching efficacy in every context and for every student, so there is new information on the **Every Student Succeeds Act (ESSA)**. Also, the section on research now includes **mixed methods** (complementary methods) (see Table 1.2) and **evidence-based practice**.
- **Chapter 2:** New information on the **brain** and **brain imaging techniques, synaptic plasticity, brain development in childhood and adolescence, and implications for teaching**. Also, there is greater critical analysis of Piaget's and Vygotsky's theories.

- **Chapter 3:** Updated section on **physical changes in puberty, cultural differences in play, childhood obesity, eating disorders** and the Web sites that promote them, **parenting, aggression, racial identity, and self-concept.**
- **Chapter 4:** New sections on **biases in labeling, neuroscience and intelligence, problems with learning styles, ADHD, student drug use, seizure disorders and other serious health concerns, and autism spectrum disorders.**
- **Chapter 5:** New information on **language development, emergent literacy, language diversity, and bilingual education.**
- **Chapter 6:** New coverage of **intersectionality, ethnicity and race, prejudice, expanded coverage of stereotype threat, gender, gender identity, sexual orientation, and creating culturally compatible classrooms.**
- **Chapter 7:** Expanded coverage of **ethical issues in behavioral approaches, reasons for classroom disruptions, and teaching implications** of behavioral learning.
- **Chapter 8:** Updated coverage of the **brain and cognitive learning, multitasking, working memory and cognitive load, concept teaching, desirable difficulty, effective practice, and teaching implications** of cognitive learning theories.
- **Chapter 9:** All new section on **teaching for complex learning and robust knowledge, updated discussion of metacognitive strategies, retrieval practice, worked examples, argumentation, and critical thinking.**
- **Chapter 10:** New sections on **designing learning environments, facilitating in constructivist classrooms, scaffolding, asking and answering deep questions, and the flipped classroom.** Updated discussion of **collaboration, learning in a digital world, and computational thinking.**
- **Chapter 11:** Updated coverage of **modeling, self-efficacy and agency, teacher efficacy, self-regulated learning, and emotional self-regulation.** New section on **grit.**
- **Chapter 12:** Chapter reorganized around **five broad themes** in motivation. Updated treatment of **expectancy-value-cost theory.** New section on **mindsets.** Updated material on **flow** and on the **TARGET framework for motivation.**
- **Chapter 13:** New sections on the role of **relationships, social skills, and mentoring in classroom management.** Updated material on **dealing with discipline problems, bullying and cyberbullying, restorative justice, and culturally responsive classroom management.**
- **Chapter 14:** Updated research on **teaching, homework, and teacher expectations** as well as new sections on **learning targets, the Common Core, asking deep questions, and giving feedback.**
- **Chapter 15:** New sections on **formative and interim assessment, guidance for using different types of test formats and rubrics, and assessing complex thinking.** Updated material on **discussing test results with families, controversies around high-stakes testing, value-added assessment, and PARCC and SBAC tests.**

A CRYSTAL CLEAR PICTURE OF THE FIELD AND WHERE IT IS HEADED

The fourteenth edition maintains the lucid writing style for which the book is renowned. The text provides accurate, up-to-date coverage of the foundational areas within educational psychology: learning, development, motivation, teaching, and assessment, combined with intelligent examinations of emerging trends in the field and society that affect student learning, such as student diversity, inclusion of students with special learning needs, education and neuroscience, educational policy, and technology.

MyLab for Education

The most visible change in the fourteenth edition (and certainly one of the most significant changes) is the expansion of the digital learning and assessment resources embedded in the etext. Designed to bring you more directly into the world of K–12 classrooms

and to help you see the very real impact that educational psychology concepts have on learning and development, these digital learning and assessment resources also:

- Provide you with practice using educational psychology concepts in teaching situations.
- Help you and your instructor see how well you understand the concepts presented in the book and the media resources.
- Help you more deeply think about and process educational psychology and how to use it as a teacher (and as a learning tool).

The online resources in MyLab for Education include:

- **Video Examples.** In almost all chapters, embedded videos provide illustrations of educational psychology principles or concepts in action. These video examples most often show students and teachers working in classrooms. Sometimes they show students or teachers describing their thinking or experiences.

MyLab Education
Video Example 2.1

The children in this video are learning something new about growth by observing a tadpole as it changes from day to day. They can assimilate the idea that the tadpole grows legs, but they need to accommodate their concept of growth to understand why the tadpole's tail gets smaller.

- **Podcasts.** In all chapters, AnitaTalks podcasts provide direct links to relevant selections from Anita Talks About Teaching, a series of podcasts in which Dr. Woolfolk discusses how the chapters in this text relate to the profession of teaching.

MyLab Education
Podcast 2.1

Listen as textbook author Anita Woolfolk talks about brain-based education. What does this mean? Are there some clear implications for teachers or is it still too early to say?

- **Self-Checks.** Throughout the chapters you will find MyLab for Education: Self-Check quizzes. There are four to six quizzes in each chapter, with one at the end of each major text section. They are meant to help you assess how well you have mastered the concepts covered in the section you just read. These self-checks are made up of self-grading multiple-choice items that not only provide feedback on whether you answered the questions correctly or incorrectly, but also offer with rationales for both correct and incorrect answers.

MyLab Education [Self-Check 2.5](#)

- **Application Exercises.** Also at the end of each major section, you can find one or two application exercises that can challenge you to use chapter content to reflect on teaching and learning in real classrooms. The questions you answer in these exercises are usually constructed-response items. Once you provide your own answers to the questions, you will receive feedback in the form of model answers written by experts.

- **Practice for Your Licensure Exam.** Every chapter ends with an exercise that can give you an opportunity to apply the chapter's content while reading a case study and then answering multiple-choice and constructed-response questions similar to those that appear on many teacher licensure tests. By clicking on the MyLab for Education hotlink at the end of a Connect and Extend to Licensure exercise, you can complete the activity online and get feedback about your answers.

95 CHAPTER TWO

▼ CONNECT AND EXTEND TO LICENSURE

MULTIPLE-CHOICE QUESTIONS

1. Classes at River Community High School begin at 7:30 a.m. The new principal, however, wanted to start classes at a later time of 8:00 a.m. The principal submitted a proposal to the local education office and provided several reasons for the recommended change. Imagine you were the officer tasked to decide the principal and to verify the reasons cited by the principal. In your review, you found that several of the reasons made claims that were not supported by research. EXCEPT
 - A. Teenagers undergo neurological development that does their biological clock, making many of them unable to sleep before midnight, and hence, they would not get the ideal 9 hours of sleep if school started at 7:30 a.m.
 - B. Research consistently and unequivocally shows that schools that start later in the day (e.g., 8:00 a.m.) have better academic performance than schools that begin early (e.g., 7:30 a.m.).
 - C. Schools that begin too early may lead many students to experience sleep deprivation, and sleep deprivation is related to failure in memory retention, so, performance would suffer.
 - D. It is better to give students more time for breakfast and less time for lunch, given that the former supplements students with nutrients needed to energize their day, while the latter generally leads to drowsiness in afternoon classes.
2. Miss McClintock discovered that five of the children in her class were developmentally advanced. All of the students' language skills were exploding! Although many of the students still had trouble drawing, a link appeared to understand that, by drawing, students could be happy. Finally, there was even one child who could solve construction problems. According to Piagetian theory, in what stage are the children in Miss McClintock's class?
 - A. Formal operations
 - B. Concrete operations
 - C. Preoperational
 - D. Sensorimotor
3. You want to maximize your students' learning outcomes and you recently read a book written by Vygotsky. Which of the following strategies would LEAST likely be employed by you?
 - A. Whenever appropriate, you will utilize technological tools and interactive devices to assist with your teaching.
 - B. You will put students in the same classrooms into groups for discussions to facilitate their learning of challenging topics.

- C. You will assign additional challenge questions at the end of each class and provide appropriate feedback to your students in solving these.
 - D. You will encourage students to think about complex problems and talk to themselves about the issues they are working on, before seeking answers from them.
4. Which of the following is TRUE about cognitive development and teaching?
 - A. Teachers should provide more social interactions and reduce physical stimulation in the classroom because the former is more important for early cognitive development.
 - B. Students will benefit if most of their learning comes through direct instructions from a more experienced teacher.
 - C. Repeatedly teaching students what they already know is important to reinforce their memory and to consolidate their knowledge.
 - D. Providing students with challenging questions will not stimulate them, but keep them engaged, if appropriate supports are given.

CONSTRUCTED-RESPONSE QUESTIONS

Case

While planning for instruction, Mr. Getting remembered that students should be neither bored nor frustrated. Although this made sense to him, he had a hard time he would compromise for the diverse group of students he had in his second-period language arts class. Some students had a fluency with the English language, and other students planned no participation in the school's annual Shakespearean play. He knew that by grouping students of mixed ability, he could maximize the use of the talents of his knowledgeable students to assist the less advanced students. He also remembered that without guidance, students might not accomplish anything.

5. Explain the theory of learning Mr. Getting is mostly drawing on, and identify the individual student with it.

6. What is the term for the assistance that the more knowledgeable students may provide to the less advanced students in order to help them succeed? List some strategies these students might use to assist their peers.

MyLab Education Licensure Exam

- **Classroom Management Simulations.** In the left-hand navigation bar of MyLab for Education, you will be able to access interactive simulations that engage you in decision making about classroom management strategies. These interactive cases focus on the classroom management issues teachers most frequently encounter on a daily basis. Each simulation presents a challenge scenario at the beginning and then offers a series of choices to solve each challenge. Along the way you receive mentor feedback on your choices and have the opportunity to make better choices if necessary.
- **Study Modules.** In the left-hand navigation bar of MyLab for Education, you will also find a set of Study Modules. These interactive, application-oriented modules provide opportunities to learn foundational educational psychology concepts in ways other than reading about them. The modules present content through screen-capture videos that include animations, worked examples, and classroom videos. Each module consists of three parts. In the first part, begin with the Learn section that presents several key concepts and strategies. Then work through the problems in the Apply section. These will give you practice applying the concepts and principles to actual teaching and learning scenarios. The third part of each module is a multiple-choice test in the Assess section. This test includes higher-order questions that assess not only what you can remember about the module's content but also how well you can apply the concepts and strategies you've learned to real-life classroom situations.
- **Video Analysis Tool.** Our widely anticipated Video Analysis Tool is also available in the left-hand navigation bar of MyLab for Education. The Video Analysis Tool helps you build your skills in analyzing teaching. Exercises provide classroom videos and rubrics to scaffold your analysis. Timestamp and commenting tools allow you to easily annotate the video and connect your observation to educational psychology concepts you have learned in the text.

Additional Text Features

With an unswerving emphasis on educational psychology's practical relevance for teachers and students in classrooms, the text is replete with current issues and debates, examples, lesson segments, case studies, and practical ideas from experienced teachers.

Point/Counterpoint sections in each chapter present two perspectives on a controversial question related to the field; topics include debates on the kinds of research that should guide education (p. 48), brain-based education (pp. 70–71), the self-esteem movement (p. 135), pills or skills for students with ADHD (p. 179), the best way to teach English language learners (p. 231), should girls and boys be taught differently? (pp. 272–273), using rewards to encourage student learning (pp. 318–319), what's wrong with multitasking? (p. 335), teaching critical thinking and problem solving (p. 395), problem-based education (pp. 424–425), are “grittier” students more successful? (p. 470–471), the value of trying to make learning entertaining (p. 512), zero tolerance (p. 560), the Common Core standards (p. 586), and holding children back (p. 642).

Guidelines appear throughout each chapter, providing concrete applications of theories or principles discussed. See, for example, pages 80, 114, 119, 166, 183, 214, 227, 256, 302, 336, 360, 391, 436, 445, 465, 513, 543, 556, 590, 602, 636, and 644.

Guidelines: Family and Community Partnerships sections offer specific guidelines for involving all families in their children's learning—especially relevant now, when demand for parental involvement is at an all-time high and the need for cooperation between home and school is critical. See, for example, pages 112, 172, 229, 400, 528, 573, 597, and 651.

Teachers' Casebook sections present students with realistic classroom scenarios at the beginning of each chapter and ask “What Would You Do?”—giving students the opportunity to apply all the important topics of the chapter to these scenarios via application questions. Students may then compare their responses to those of veteran

teachers appearing at the end of each chapter. See, for example, pages 99, 203, 287, 406–407, and 533.

Reaching Every Student sections present ideas for assessing, teaching, and motivating ALL of the students in today's inclusive classrooms. See, for example, page 93.

Lessons for Teachers are succinct and usable principles for teaching based on the research. See, for example, page 507–508.

Put Yourself in Their Place experiences develop empathy by asking students to imagine how they would feel in different situations. See pages 225, 226, 260, 306, 379, 505, and 643.

Stop and Think activities give students firsthand experience with the concept being discussed, as on pages 246, 332, 337, 493, 498, 506, 539, 583, and 638.

SUPPLEMENTARY MATERIALS

Many supplements to the textbook are available to enhance readers' learning and development as teachers.

ONLINE INSTRUCTOR'S MANUAL. Available to instructors for download at <http://www.pearsonglobaleditions.com/> is an *Instructor's Manual* with suggestions for learning activities, supplementary lectures, group activities, and additional media resources. These have been carefully selected to provide opportunities to support, enrich, and expand on what students read in the textbook.

ONLINE POWERPOINT® SLIDES. PowerPoint slides are available to instructors for download at <http://www.pearsonglobaleditions.com/>. These slides include key concept summarizations and other graphic aids to help students understand, organize, and remember core concepts and ideas.

ONLINE TEST BANK. The *Test Bank* that accompanies this text contains both multiple-choice and essay questions. Some items (lower-level questions) simply ask students to identify or explain concepts and principles they have learned. But many others (higher-level questions) ask students to apply those same concepts and principles to specific classroom situations—that is, to actual student behaviors and teaching strategies. The lower-level questions assess basic knowledge of educational psychology. But ultimately, it is the higher-level questions that can best assess students' ability to use principles of educational psychology in their own teaching practice.

TESTGEN®. TestGen is a powerful test generator available exclusively from Pearson Education publishers. Instructors install TestGen on a personal computer (Windows or Macintosh) and create their own tests for classroom testing and for other specialized delivery options, such as over a local area network or on the web. A test bank, which is also called a Test Item File (TIF), typically contains a large set of test items, organized by chapter and ready for your use in creating a test, based on the associated textbook material. Assessments—including equations, graphs, and scientific notation—can be created in either paper-and-pencil or online formats.

ACKNOWLEDGMENTS

During the years I have worked on this book, from initial draft to this most recent revision, many people have supported the project. Without their help, this text simply could not have been written.

Many educators contributed to this edition and previous editions. Ellen L. Usher (University of Kentucky) contributed her remarkable scholarship and delightful writing to revise Chapters 6 and 11. Carol Weinstein wrote the section in Chapter 13 on spaces for learning. Michael Yough (Purdue University) looked over several chapters including Chapter 5, “Language Development, Language Diversity, and Immigrant Education.” Chapter 5 was also improved by suggestions from Alan Hirvela, The Ohio State University. Jerrell Cassady, Ball State University, provided invaluable guidance for Chapter 12, “Motivation in Learning and Teaching.” The portraits of students in Chapters 1 and 6 were provided by Nancy Knapp (University of Georgia).

As I made decisions about how to revise this edition, I benefited from the ideas of colleagues around the country who took the time to complete surveys, answer my questions, and review chapters.

For their revision reviews, thanks to Karen Banks, George Mason University; Marcus Green, North Carolina State University; Cheryl Greenberg, University of North Carolina at Greensboro; Michelle Koussa, University of North Texas; Nicole Leach, Mississippi State University; and Lu Wang, Ball State University.

Many classroom teachers across the country and around the world contributed their experience, creativity, and expertise to the *Teachers’ Casebook*. I have thoroughly enjoyed my association with these master teachers, and I am grateful for the perspective they brought to the book:

AIMEE FREDETTE • Second-Grade Teacher
Fisher Elementary School, Walpole, MA
ALLAN OSBORNE • Assistant Principal
Snug Harbor Community School, Quincy, MA
BARBARA PRESLEY • Transition/Work Study Coordinator—High School Level,
BESTT Program (Baldwinsville Exceptional Student Training and Transition Program) C. W. Baker High School, Baldwinsville, NY

 Glenmount School, Baltimore, MD

On this edition, I was again privileged to work with an outstanding editorial group. Their intelligence, creativity, sound judgment, style, and enduring commitment to quality can be seen on every page of this text. Kevin Davis, Director and Publisher, guided the project from reviews to completion with the eye of an artist, the mind of a scholar, and the logistical capacity of a high-powered computer. He proved to be an excellent collaborator with a wise grasp of the field and a sense of the future. Casey Coriell, Editorial Assistant, kept everything running smoothly and kept my e-mail humming. On this edition I was fortunate to have the help of Kathy Smith. She carefully and expertly read and reread every page—and improved the writing and logic in every chapter. Her expertise and dedication set the standard for everyone in this project. Alicia Reilly was the outstanding developmental editor with the perfect combination of vast knowledge,

organizational ability, and creative thinking. The text features, *Teachers' Casebook*, and excellent pedagogical supports would not exist without her tireless efforts. Content and Media Producers Janelle Rogers, Lauren Carlson and Daniel Dwyer from Pearson and Gail Gottfried kept all aspects of the project moving forward with amazing skill, grace, and good humor. Somehow they brought sanity to what could have been chaos and fun to what might have been drudgery. Now the book is in the able hands of marketing managers Christopher Barry and Krista Clark. I can't wait to see what they are planning for me now! What a talented and creative group—I am honored to work with them all.

Finally, I want to thank my family and friends for their kindness and support during the long days and nights that I worked on this book. To my family, Marion, Bob, Eric, Suzie, Lizzie, Wayne K., Marie, Kelly, and the newest member, Amaya—you are amazing.

And of course, to Wayne Hoy, my friend, colleague, inspiration, passion, husband—you are simply the best.

—ANITA WOOLFOLK HOY

Is It Just Common Sense? 42

Helping Students 42 • Answer Based on Research 43 • Skipping Grades 43 • Answer Based on Research 43 • Students in Control 43 • Answer Based on Research 43 • Obvious Answers? 43

Using Research to Understand and Improve Learning 44

Correlation Studies 44 • Experimental

Studies 45 • ABAB Experimental

Designs 45 • Clinical Interviews and Case

Studies 45 • Ethnography 46 • The Role of Time in Research 46 • What's The Evidence? Quantitative

versus Qualitative Research 46 • Mixed Methods Research 47 • Scientifically Based Research

and Evidence-Based Practices 47 • Teachers as Researchers 47

POINT/COUNTERPOINT: What Kind of Research Should Guide Education? 48

Theories for Teaching 50

Supporting Student Learning 51

Summary and Key Terms 53

Practice Using What You Have Learned 55

Connect and Extend to Licensure 56

Teachers' Casebook—Leaving No Student Behind: What Would They Do? 57

PART I STUDENTS

CHAPTER 2

Cognitive Development 58

Teachers' Casebook—Symbols and Cymbals: What Would You Do? 58

Overview and Objectives 59

A Definition of Development 60

Three Questions Across the Theories 60

What Is the Source of Development? Nature versus Nurture 61 • What Is the Shape of Development? Continuity versus Discontinuity 61 • Timing: Is It Too Late? Critical versus Sensitive Periods 61 • Beware of Either/Or 61

General Principles of Development 62

The Brain and Cognitive Development 62

The Developing Brain: Neurons 63

The Developing Brain: Cerebral Cortex 66

Brain Development in Childhood and Adolescence 67

Putting It All Together: How the Brain Works 69
Culture and Brain Plasticity 69

POINT/COUNTERPOINT: Brain-Based Education 70

Neuroscience, Learning, and Teaching 70

Does Instruction Affect Brain Development? 70 • The Brain and Learning to Read 70 • Emotions, Learning, and the Brain 71

Lessons for Teachers: General Principles 72

Piaget's Theory of Cognitive Development 73

Influences on Development 74

Basic Tendencies in Thinking	74
Organization	74 • Adaptation 75 • Equilibration 75
Four Stages of Cognitive Development	75
Infancy: the Sensorimotor Stage	76 • Early Childhood to the Early Elementary Years: The Preoperational Stage 77
FAMILY AND COMMUNITY PARTNERSHIPS: Helping Families Care for Preoperational Children	78
Later Elementary to the Middle School Years: The Concrete-Operational Stage	78
GUIDELINES: Teaching the Concrete-Operational Child	80
High School and College: Formal Operations	80
Do We All Reach the Fourth Stage?	82
Some Limitations of Piaget's Theory	82
The Trouble with Stages	82
GUIDELINES: Helping Students to Use Formal Operations	82
Underestimating Children's Abilities	83 • Cognitive Development and Culture 83
Information Processing, Neo-Piagetian, and Neuroscience Views of Cognitive Development	84
Vygotsky's Sociocultural Perspective	85
The Social Sources of Individual Thinking	85
Cultural Tools and Cognitive Development	86
Technical Tools in a Digital Age	87 • Psychological Tools 87
The Role of Language and Private Speech	87
Private Speech: Vygotsky's and Piaget's Views Compared	88
The Zone of Proximal Development	89
Private Speech and the Zone	89 • The Role of Learning and Development 90
Limitations of Vygotsky's Theory	90
Implications of Piaget's and Vygotsky's Theories for Teachers	90
Piaget: What Can We Learn?	91
Understanding and Building on Students' Thinking	91 • Activity and Constructing Knowledge 91
Vygotsky: What Can We Learn?	92
The Role of Adults and Peers	92 • Assisted Learning 93
An Example Curriculum: Tools of the Mind	93
Reaching Every Student: Teaching in the "Magic Middle"	93
Cognitive Development: Lessons for Teachers	94
GUIDELINES: Applying Vygotsky's Ideas in Teaching	95
Summary and Key Terms	95
Practice Using What You Have Learned	97

CHAPTER 3

The Self, Social, and Moral Development 100

Teachers' Casebook—Mean Girls: What Would You Do?	100
Overview and Objectives	101
Physical Development	102
Physical and Motor Development	102
Young Children	102 • Elementary School Years 102 • The Adolescent Years 103 • Early and Later Maturing 103
GUIDELINES: Dealing with Physical Differences in the Classroom	104
Play, Recess, and Physical Activity	104
Cultural Differences in Play	105 • Exercise and Recess 105
Reaching Every Student: Inclusive Athletics	105
Challenges in Physical Development	106
Obesity	106 • Eating Disorders 107
GUIDELINES: Supporting Positive Body Images in Adolescents	108
Bronfenbrenner: The Social Context for Development	108
The Importance of Context and the Bioecological Model	108
Families	109
Family Structure	109 • Parenting Styles 110 • Culture and Parenting 111
FAMILY AND COMMUNITY PARTNERSHIPS: Connecting with Families	112
Attachment	112 • Divorce 112
GUIDELINES: Helping Children of Divorce	114
Peers	114
Cliques	115 • Crowds 115 • Peer Cultures 115
Friendships	115 • Popularity 116
Causes and Consequences of Rejection	117
Aggression	117 • Relational Aggression 118
Media, Modeling, and Aggression	118
GUIDELINES: Dealing with Aggression and Encouraging Cooperation	119
Video Games and Aggressive Behavior	119
Reaching Every Student: Teacher Support	120
Academic and Personal Caring	120
Teachers and Child Abuse	121
Society and Media	122

Identity and Self-Concept 123

Erikson: Stages of Psychosocial Development 124

The Preschool Years: Trust, Autonomy, and Initiative 124 • The Elementary and Middle School Years: Industry versus Inferiority 125

GUIDELINES: Encouraging Initiative and Industry 126

Adolescence: The Search for Identity 127 • Identity and Technology 128 • Beyond the School Years 128

Racial and Ethnic Identity 128

GUIDELINES: Supporting Identity Formation 129Multidimensional and Flexible Ethnic Identities 129
Black Racial Identity: Outcome and Process 130 • Racial and Ethnic Pride 131

Self-Concept 131

The Structure of Self-Concept 131 • How Self-Concept Develops 132 • Self-Concept and Achievement 133

Sex Differences in Self-Concept of Academic

Competence 133

Self-Esteem 134

POINT/COUNTERPOINT: What Should Schools Do to Encourage Students' Self-Esteem? 135**Understanding Others and Moral Development 135**

Theory of Mind and Intention 136

Moral Development 136

Kohlberg's Theories of Moral Development 136
• Criticisms of Kohlberg's Theory 137

Moral Judgments, Social Conventions, and Personal Choices 138

Moral versus Conventional Domains 138 • Implications for Teachers 139

Beyond Reasoning: Haidt's Social Intuitionist Model of Moral Psychology 140

Moral Behavior and the Example of Cheating 141

Who Cheats? 141 • Dealing with Cheating 143

Personal/Social Development: Lessons for Teachers 143**Summary and Key Terms 143****Practice Using What You Have Learned 145****Connect and Extend to Licensure 146****Teachers' Casebook—Mean Girls: What Would They Do? 147****CHAPTER 4****Learner Differences and Learning Needs 148****Teachers' Casebook—Including Every student: What Would You Do? 148****Overview and Objectives 149****Intelligence 150**

Language and Labels 150

Disabilities and Handicaps 150 • Person-First Language 151 • Possible Biases in the Application of Labels 152

What Does Intelligence Mean? 152

Intelligence: One Ability or Many? 153

Another View: Gardner's Multiple Intelligences 153

What Are These Intelligences? 154 • Critics of Multiple Intelligences Theory 154 • Gardner Responds 154 • Multiple Intelligences Go to School 155

Multiple Intelligences: Lessons for Teachers 156

Another View: Sternberg's Successful Intelligence 156

Neuroscience and Intelligence 157

Measuring Intelligence 157

Binet's Dilemma 158 • What Does an IQ Score Mean? 158 • Group versus Individual IQ Tests 158 • The Flynn Effect: Are We Getting Smarter? 158

GUIDELINES: Interpreting IQ Scores 159

Intelligence and Achievement 159

Gender Differences in Intelligence and Achievement 160

Heredity or Environment? 160

Learning to Be Intelligent: Being Smart About IQ 161

Creativity: What It Is and Why It Matters 161

Assessing Creativity 162

OK, But So What: Why Does Creativity Matter? 163

What Are the Sources of Creativity? 163

Creativity and Cognition 164 • Creativity and Diversity 164

Creativity in the Classroom 164

Brainstorming 165 • Creative Schools 165

GUIDELINES: Applying and Encouraging Creativity 166**Learning Styles 167**

Learning Styles/Preferences 167

Cautions About Learning Styles 167 • The Value of Considering Learning Styles 168

Beyond Either/Or 169

Individual Differences and the Law 169

IDEA 169

Least Restrictive Environment 170 • Individualized Education Program 170 • The Rights of Students and Families 171

Section 504 Protections 172

FAMILY AND COMMUNITY PARTNERSHIPS: Productive Conferences 172**Students with Learning Challenges 173**

Neuroscience and Learning Challenges 173

Students with Learning Disabilities 174

Student Characteristics 175 • Teaching Students with Learning Disabilities 176

Students with Hyperactivity and Attention Disorders	177
Definitions	178 • Treating ADHD with Drugs 178
• Alternatives/Additions to Drug Treatments	178
POINT/COUNTERPOINT: Pills or Skills for Children with ADHD?	179
Lessons for Teachers: Learning Disabilities and ADHD	179
Students with Communication Disorders	180
Speech Disorders	180 • Language Disorders 181
Students with Emotional or Behavioral Difficulties	182
Suicide	183
GUIDELINES: Disciplining Students with Emotional Problems	183
Drug Abuse	185 • Prevention 185
Students with Intellectual Disabilities	186
GUIDELINES: Teaching Students with Intellectual Disabilities	187
Students with Health and Sensory Impairments	187
Cerebral Palsy and Multiple Disabilities	187
Seizure Disorders (Epilepsy)	188 • Other Serious Health Concerns: Asthma, Sickle Cell Disease, and Diabetes 188 • Students with Vision Impairments 189 • Students Who Are Deaf 189
Autism Spectrum Disorders and Asperger Syndrome	190
Interventions	191
Response to Intervention	191
Students Who Are Gifted and Talented	194
Who Are These Students?	194
What Is the Origin of These Gifts?	195 • What Problems Do Students Who Are Gifted Face? 195
Identifying Students Who Are Gifted and Talented	196
Recognizing Gifts and Talents	196
Teaching Students with Gifts and Talents	197
Acceleration	198 • Methods and Strategies 198
Summary and Key Terms	199
Practice Using What You Have Learned	201
Connect and Extend to Licensure	202
Teachers' Casebook—Including Every Student: What Would They Do?	203

CHAPTER 5

Language Development, Language Diversity, and Immigrant Education 204

Teachers' Casebook—Cultures Clash in the Classroom: What Would You Do? 204

Overview and Objectives 205

The Development of Language 206

What Develops? Language and Cultural Differences 206

The Puzzle of Language 206 • Beware of Either/Or Choices 207

When and How Does Language Develop? 207

Sounds and Pronunciation 207 • Vocabulary and Meaning 207 • Grammar and Syntax 208 • Pragmatics: Using Language in Social Situations 209 • Metalinguistic Awareness 209

Emergent Literacy 209

Inside-Out and Outside-In Skills 210 • Building a Foundation 211 • When There Are Persistent Problems 212

Emergent Literacy and Language Diversity 213

Languages and Emergent Literacy 213 • Bilingual Emergent Literacy 213

GUIDELINES: Supporting Language and Promoting Literacy 214

Diversity in Language Development 215

Dual-Language Development 215

Second-Language Learning 215 • Benefits of Bilingualism 216 • Language Loss 216

Signed Languages 217

What Is Involved in Being Bilingual? 217

Contextualized and Academic Language 218

GUIDELINES: Promoting Language Learning 220

Dialect Differences in the Classroom 221

Dialects 221

Dialects and Pronunciation 221 • Dialects and Teaching 221

Genderlects 222

Teaching Immigrant Students 222

Immigrants and Refugees 223

Classrooms Today 224

Four Student Profiles 224

Generation 1.5: Students in Two Worlds 225

Affective and Emotional/Social Considerations 226

Working with Families: Using the Tools of the Culture 226

GUIDELINES: Providing Emotional Support and Increasing Self-Esteem for Students Who Are ELLs 227

Funds of Knowledge and Welcome Centers 227

Student-Led Conferences 228

FAMILY AND COMMUNITY PARTNERSHIPS: Welcoming All Families 229

Teaching Immigrant Students Who Are English Language Learners 230

Two Approaches to English Language Learning 230

• Research on Bilingual Education 230

POINT/COUNTERPOINT: What Is the Best Way to Teach Students Who Are ELLs? 231

- Visual Strategies 232 • Literature Response Groups 232
- Bilingualism for All: Two-Way Immersion 233
- Sheltered Instruction 233

Special Challenges: Students Who Are English Language Learners with Disabilities and Special Gifts 236

- Students Who Are English Language Learners with Disabilities 237
- Reaching Every Student: Recognizing Giftedness in Bilingual Students 239

Summary and Key Terms 239

Practice Using What You Have Learned 241

Connect and Extend to Licensure 242

Teachers' Casebook—Cultures Clash in the Classroom: What Would They Do? 243

CHAPTER 6

Culture and Diversity 244

Revised by Ellen L. Usher

Teachers' Casebook—White Girls Club: What Would You Do? 244

Overview and Objectives 245

Today's Diverse Classrooms 246

- American Cultural Diversity 246
- Meet Two More Students 248
- Cautions: Interpreting Cultural Differences 249
- Cultural Conflicts and Compatibilities 249 • Dangers in Stereotyping 250

Economic and Social Class Differences 250

- Social Class and Socioeconomic Status 250
- Extreme Poverty: Homeless and Highly Mobile Students 252
- Poverty and School Achievement 252
- Health, Environment, and Stress 254 • Low Expectations—Low Academic Self-Concept 254 • Peer Influences and Resistance Cultures 254 • Home Environment and Resources 255 • Summer Setbacks 255

GUIDELINES: Teaching Students Who Live in Poverty 256

- Tracking: Poor Teaching 256

Ethnicity and Race in Teaching and Learning 257

- Terms: Ethnicity and Race 257
- Ethnic and Racial Differences in School Achievement 258
- The Legacy of Inequality 260
- What Is Prejudice? 261 • The Development of Prejudice 261 • From Prejudice to Discrimination 263
- Stereotype Threat 264

- Who Is Affected by Stereotype Threat? 264 • Short-Term Effects: Test Performance 264 • Long-Term Effects: Disidentification 265 • Combating Stereotype Threat and Discrimination 266

Gender in Teaching and Learning 267

- Sex and Gender 267
- Gender Identity 267
- Gender Roles 268
- Gender Bias in Curriculum Materials and Media 270
- Gender Bias in Teaching 270
- Sexual Orientation 271

POINT/COUNTERPOINT: Should Girls and Boys Be Taught Differently? 272

- Discrimination Based on Gender Expression and Sexual Orientation 273

GUIDELINES: Avoiding Gender Bias in Teaching 274

Creating Culturally Compatible Classrooms 276

- Culturally Relevant Pedagogy 277
- Self-Agency Strand 279 • Relationship Strand 279
- Diversity in Learning 279
- Social Organization 279 • Cultural Values and Learning Preferences 280 • Cautions (Again) About Learning Styles/Preferences Research 280 • Sociolinguistics 281 • Cultural Discontinuity 281
- Lessons for Teachers: Teaching Every Student 281
- Know Yourself 282 • Know Your Students 282 • Respect Your Students 282 • Teach Your Students 283

GUIDELINES: Culturally Relevant Teaching 283

Summary and Key Terms 284

Practice Using What You Have Learned 285

Connect and Extend to Licensure 286

Teachers' Casebook—White Girls Club: What Would They Do? 287

PART II LEARNING AND MOTIVATION

CHAPTER 7

Behavioral Views of Learning 288

Teachers' Casebook—Sick of Class: What Would You Do? 288

Overview and Objectives 289

Understanding Learning 290

- Ethical Issues 291
- Goals 291 • Strategies 291
- Learning Is Not Always What It Seems 291

Early Explanations of Learning: Contiguity and Classical Conditioning 292

GUIDELINES: Applying Classical Conditioning	294
Operant Conditioning: Trying New Responses	294
Types of Consequences	295
Reinforcement	295 • Punishment 296
Neuroscience of Reinforcement and Punishment	297
Reinforcement Schedules	298
Extinction	299
Antecedents and Behavior Change	299
Effective Instruction Delivery	299 • Cueing 300
Putting It All Together: Applied Behavior Analysis	300
Methods for Encouraging Behaviors	301
Reinforcing with Teacher Attention	301 • Selecting Reinforcers: The Premack Principle 301
GUIDELINES: Applying Operant Conditioning: Using Praise Appropriately	302
Shaping	303 • Positive Practice 303
GUIDELINES: Applying Operant Conditioning: Encouraging Positive Behaviors	304
Contingency Contracts, Token Reinforcement, and Group Consequences	304
Contingency Contracts	304 • Token Reinforcement Systems 305 • Group Consequences 306
Handling Undesirable Behavior	308
Negative Reinforcement	308 • Reprimands 309
• Response Cost	309 • Social Isolation 309
• Some Cautions About Punishment	309
GUIDELINES: Applying Operant Conditioning: Using Punishment	310
Reaching Every Student: Severe Behavior Problems	311
Current Applications: Functional Behavioral Assessment, Positive Behavior Supports, and Self-Management	311
Discovering the “Why”: Functional Behavioral Assessments	312
Positive Behavior Supports	313
Self-Management	315
Goal Setting	315 • Monitoring and Evaluating Progress 315
FAMILY AND COMMUNITY PARTNERSHIPS: Applying Operant Conditioning: Student Self-Management	316
Self-Reinforcement	316
Challenges and Criticisms	317
Beyond Behaviorism: Bandura’s Challenge and Observational Learning	317
Enactive and Observational Learning	317 • Learning and Performance 317

POINT/COUNTERPOINT: Should Students Be Rewarded for Learning? 318

Criticisms of Behavioral Methods 318
Behavioral Approaches: Lessons for Teachers 319

Summary and Key Terms 320

Practice Using What You Have Learned 322

Connect and Extend to Licensure 323

Teachers’ Casebook—Sick of Class: What Would They Do? 324

CHAPTER 8

Cognitive Views of Learning 326

Teachers’ Casebook—Remembering the Basics: What Would You Do? 326

Overview and Objectives 327

Elements of the Cognitive Perspective 328

The Brain and Cognitive Learning 328
The Importance of Knowledge in Cognition 329
General and Specific Knowledge 329 • Declarative, Procedural, and Self-Regulatory Knowledge 330

Cognitive Views of Memory 330

Sensory Memory 332
Capacity, Duration, and Contents of Sensory Memory 332 • Perception 332 • The Role of Attention 334 • Attention and Multitasking 334

POINT/COUNTERPOINT: What’s Wrong with Multitasking? 335

Attention and Teaching 335

GUIDELINES: Gaining and Maintaining Attention 336

Working Memory 337

Capacity of Working Memory 337 • The Central Executive 338 • The Phonological Loop 338 • The Visuospatial Sketchpad 339 • The Episodic Buffer 339 • The Duration and Contents of Working Memory 339

Cognitive Load and Retaining Information 339

Two Kinds of Cognitive Load 340 • Retaining Information in Working Memory 340 • Levels of Processing Theory 341 • Forgetting 342

Individual Differences in Working Memory 342

Developmental Differences 342 • Individual Differences 343

Is Working Memory Really Separate? 343

Long-Term Memory 344

Capacity and Duration of Long-Term Memory 344
Contents of Long-Term Memory: Explicit (Declarative) Memories 345

Propositions and Propositional Networks	345
• Images	345 • Two Are Better Than One: Words and Images
346 • Concepts	346 • Prototypes, Exemplars, and Theory-Based Categories
346 • Teaching Concepts	347 • Schemas
347 • Episodic Memory	349
Contents of Long-Term Memory: Implicit Memories	349
Retrieving Information in Long-Term Memory	350
Spreading Activation	351 • Reconstruction
351 • Forgetting and Long-Term Memory	351
Individual Differences in Long-Term Memory	352
Teaching for Deep, Long-Lasting Knowledge: Basic Principles and Applications	352
Constructing Declarative Knowledge: Making Meaningful Connections	352
Elaboration	352
FAMILY AND COMMUNITY PARTNERSHIPS: Organizing Learning	353
Organization	353 • Imagery
353 • Context	355 • Desirable Difficulty
355 • Effective Practice	355
Reaching Every Student: Make it Meaningful	356
Mnemonics	356
If You Have to Memorize . . .	357
Lessons for Teachers: Declarative Knowledge	358
Development of Procedural Knowledge	359
Automated Basic Skills	359
GUIDELINES: Helping Students Understand and Remember	360
Domain-Specific Strategies	361
Summary and Key Terms	361
Practice Using What You Have Learned	363
Connect and Extend to Licensure	364
Teachers' Casebook—Remembering the Basics: What Would They Do?	364

CHAPTER 9

Complex Cognitive Processes 366

Teachers' Casebook—Uncritical Thinking: What Would You Do?	366
Overview and Objectives	367
Metacognition	368
Metacognitive Knowledge and Regulation	368
Individual Differences in Metacognition	369
Lessons for Teachers: Developing Metacognition	370

Metacognitive Development for Younger Students	370 • Metacognitive Development for Secondary and College Students (Like You)
371	
Learning Strategies	372
Being Strategic About Learning	372
Deciding What Is Important	374 • Summaries
374 • Underlining and Highlighting	374 • Taking Notes
374	
Visual Tools for Organizing	375
Retrieval Practice: Powerful But Underused	377
Reading Strategies	378
Applying Learning Strategies	378
Appropriate Tasks	378 • Valuing Learning
378 • Effort and Efficacy	379
Reaching Every Student: Teaching How to Learn	379
Problem Solving	379
Identifying: Problem Finding	380
Defining Goals and Representing the Problem	381
Focusing Attention on What Is Relevant	381 • Understanding the Words
381 • Understanding the Whole Problem	382 • Translation and Schema Training: Direct Instruction in Schemas
383 • Translation and Schema Training: Worked Examples	384 • Worked Examples and Embodied Cognition
385 • The Results of Problem Representation	386
Searching for Possible Solution Strategies	386
Algorithms	386 • Heuristics
387	
Anticipating, Acting, and Looking Back	387
Factors That Hinder Problem Solving	388
Some Problems with Heuristics	388
GUIDELINES: Applying Problem Solving	389
Expert Knowledge and Problem Solving	390
Knowing What Is Important	390 • Memory for Patterns and Organization
390 • Procedural Knowledge	390 • Planning and Monitoring
390	
GUIDELINES: Becoming an Expert Student	391
Critical Thinking and Argumentation	392
What Critical Thinkers Do: Paul and Elder Model	392
Applying Critical Thinking in Specific Subjects	394
Argumentation	394
Two Styles of Argumentation	394
POINT/COUNTERPOINT: Should Schools Teach Critical Thinking and Problem Solving?	395
Lessons for Teachers	396
Teaching for Transfer	397
The Many Views of Transfer	397
Teaching for Positive Transfer	398
What Is Worth Learning?	398 • Lessons for Teachers: Supporting Transfer
399 • Stages of Transfer for Strategies	399
FAMILY AND COMMUNITY PARTNERSHIPS: Promoting Transfer	400

Bringing It All Together: Teaching for Complex Learning and Robust Knowledge 400

What Is Robust Knowledge? 400

Recognizing and Assessing Robust Knowledge 401

Teaching for Robust Knowledge 401

Practice 402 • Worked Examples 402

• Analogies 402 • Self-Explanations 402

Summary and Key Terms 403**Practice Using What You Have Learned 405****Connect and Extend to Licensure 405****Teachers' Casebook—Uncritical Thinking: What Would They Do? 406****CHAPTER 10****Constructivism and Designing Learning Environments 408****Teachers' Casebook—Learning to Cooperate: What Would You Do? 408****Overview and Objectives 409****Cognitive and Social Constructivism 410**

Constructivist Views of Learning 410

Cognitive Constructivism 411 • Social Constructivism 412

How Is Knowledge Constructed? 412

Knowledge: Situated or General? 412

Common Elements of Constructivist Student-Centered Teaching 414

Complex Learning Environments and Authentic

Tasks 414 • Social Negotiation 415 • Multiple

Perspectives and Representations of Content 415

• Understanding the Knowledge Construction

Process 415 • Student Ownership of Learning 415

Designing Constructivist Learning Environments 415

Assumptions to Guide the Design of Learning Environments 416

Facilitating in a Constructivist Classroom 416

Scaffolding 417 • Advance Organizers as Scaffold-

ing 418 • Facilitating Through Asking and Answering

Deep Questions 419

GUIDELINES: Facilitating Deep Questioning 420

Inquiry and Problem-Based Learning 420

Examples of Inquiry 421 • Problem-Based Learn-

ing 421 • Research on Inquiry and Problem-Based

Learning 423 • Being Smart About Problem-Based

Learning 423

POINT/COUNTERPOINT: Are Inquiry and Problem-Based Learning Effective Teaching Approaches? 424

Cognitive Apprenticeships and Reciprocal Teaching 424

Cognitive Apprenticeships in Reading: Reciprocal

Teaching 425 • Applying Reciprocal Teaching 426

Collaboration and Cooperation 426

Collaboration, Group Work, and Cooperative

Learning 427 • Beyond Groups to Cooperation 427

• What Can Go Wrong: Misuses of Group Learning 428

Tasks for Cooperative Learning 430

Highly Structured, Review, and Skill-Building

Tasks 430 • Ill-Structured, Conceptual, and Problem-

Solving Tasks 430 • Social Skills and Communication

Tasks 430

Setting Up Cooperative Groups 431

Assigning Roles 431 • Giving and Receiving

Explanations 432

Designs for Cooperation 432

Reciprocal Questioning 433 • Jigsaw 434

• Constructive/Structured Controversies 434

Reaching Every Student: Using Cooperative Learning

Wisely 435

GUIDELINES: Using Cooperative Learning 436

Dilemmas of Constructivist Practice 436

Designing Learning Environments in a Digital World 438

Technology and Learning 438

Technology-Rich Environments 438 • Virtual Learning

Environments 439 • Personal Learning Environ-

ments 439 • Immersive Virtual Learning Environ-

ments 440 • Games 440

Developmentally Appropriate Computer Activities for Young Children 441

Computational Thinking and Coding 442

GUIDELINES: Using Computers 443

Media/Digital Literacy 444

GUIDELINES: Supporting the Development of Media Literacy 445

The Flipped Classroom 446

Summary and Key Terms 447**Practice Using What You Have Learned 449****Connect and Extend to Licensure 450****Teachers' Casebook—Learning to Cooperate: What Would They Do? 451****CHAPTER 11****Social Cognitive Views of Learning and Motivation 452**

Revised by Ellen L Usher

Teachers' Casebook—Failure to Self-Regulate: What Would You Do? 452**Overview and Objectives 453**

Social Cognitive Theory 454

A Self-Directed Life: Albert Bandura 454

Beyond Behaviorism 454

Triadic Reciprocal Causality 455

Modeling: Learning by Observing Others 457

Elements of Observational Learning 458

Attention 458 • Retention 458 • Production 458 • Motivation and Reinforcement 459

Observational Learning in Teaching 459

Directing Attention 459 • Fine Tuning Already-Learned Behaviors 460 • Strengthening or Weakening Inhibitions 460 • Teaching New Behaviors 460 • Arousing Emotion 460

GUIDELINES: Using Observational Learning 461**Agency and Self-Efficacy 462**

Self-Efficacy, Self-Concept, and Self-Esteem 462

Sources of Self-Efficacy 463

Self-Efficacy in Learning and Teaching 464

GUIDELINES: Encouraging Self-Efficacy 465

Teachers' Sense of Efficacy 466

Self-Regulated Learning: Skill and Will 467

What Influences Self-Regulation? 468

Knowledge 468 • Motivation 469 • Volition 469

POINT/COUNTERPOINT: Are "Grittier" Students More Successful? 470

Development of Self-Regulation 472

A Social Cognitive Model of Self-Regulated Learning 472

Reaching Every Student: Examples of Self-Regulation in Two Classrooms 474

Writing 474 • Math Problem Solving 475

Technology and Self-Regulation 475

Another Approach to Self-Regulation: Cognitive Behavior Modification 476

Emotional Self-Regulation 477

GUIDELINES: Encouraging Emotional Self-Regulation 479**Teaching Toward Self-Efficacy and Self-Regulated Learning 479**

Teacher Stress, Efficacy, and Self-Regulated Learning 479

Designing Classrooms for Self-Regulation 480

Complex Tasks 480

Control 481

LEARNING, TEACHING, AND EDUCATIONAL PSYCHOLOGY

WHAT WOULD YOU DO?

TEACHERS' CASEBOOK: Leaving No Student Behind

It is your second year as a teacher in the Lincoln East school district. Over the last 4 years, the number of students from immigrant families has increased dramatically in your school. In your class, you have two students who speak Somali, one Hmong, one Farsi, and four Spanish speakers. Some of them know a little English, but many have very few words other than "OK." If there had been more students from each of the language groups, the district would have given your school additional resources and special programs in each language, providing you extra help, but there are not quite enough students speaking most of the languages to meet the requirements. In addition, you have several students with special needs; learning disabilities, particularly problems in reading, seem to be the most common. Your state and district require you to prepare *all* your students for the achievement tests in the spring, and the national emphasis is on readiness for college and career by the end of high school—for *everyone*. Your only possible extra resource is a student intern from the local college.

CRITICAL THINKING

- What would you do to help all your students to progress and prepare for the achievement tests?
- How would you make use of the intern so that both she and your students learn?
- How could you involve the families of your non-English-speaking students and students with learning disabilities to support their children's learning?

Anita Woolfolk Hoy

OVERVIEW AND OBJECTIVES

Like many students, you may begin this course with a mixture of anticipation and wariness. Perhaps you are required to take educational psychology as part of a program in teacher education, speech therapy, nursing, or counseling. You may have chosen this class as an elective. Whatever your reason for enrolling, you probably have questions about teaching, schools, students—or even about yourself—that you hope this course may answer. I have written the 14th edition of *Educational Psychology* with questions such as these in mind.

In this first chapter, we begin with the state of education in today's world. Teachers have been both criticized as ineffective and lauded as the best hope for young people. Do teachers make a difference in students' learning? What characterizes good teaching—how do truly effective teachers think and act? What do they believe about students, learning, and themselves? When you are aware of the challenges and possibilities of teaching and learning today, you can appreciate the contributions of educational psychology.

After a brief introduction to the world of the teacher, we turn to a discussion of educational psychology itself. How can principles identified by educational psychologists benefit teachers, therapists, parents, and others who are interested in teaching and learning? What exactly is the content of educational psychology, and where does this information come from? Finally, we consider an overview of a model that organizes research in educational psychology to identify the key student and school factors related to student learning (J. Lee & Shute, 2010). My goal is that you will become a confident and competent beginning teacher, so by the time you have completed this chapter, you should be able to:

- Objective 1.1 Describe the key elements of the No Child Left Behind Act and its successor, the Every Student Succeeds Act, and discuss the continuing impact of testing and accountability for teachers and students.
- Objective 1.2 Discuss the essential features of effective teaching, including different frameworks describing what good teachers do.
- Objective 1.3 Describe the methods used to conduct research in the field of educational psychology and the kinds of questions each method can address.
- Objective 1.4 Recognize how theories and research in development and learning are related to educational practice.

Summary and Key Terms

Teachers' Casebook—Leaving No Student Behind: What Would They Do?

LEARNING AND TEACHING TODAY

Welcome to my favorite topic—educational psychology—the study of development, learning, motivation, teaching, and assessment in and out of schools. I believe this is one of the most important courses you will take to prepare for your future as an educator in the classroom or the consulting office, whether your “students” are children or adults learning how to read or individuals discovering how to improve their diets. In fact, there is evidence that new teachers who have course work in development and learning are twice as likely to stay in teaching (National Commission on Teaching and America’s Future, 2003). This may be a required course for you, so let me make the case for educational psychology, first by stepping into classrooms today.

Students Today: Dramatic Diversity and Remarkable Technology

Who are the students in American classrooms today? Here are a few statistics about the United States.

- The United States is a land of immigrants. About 25% of U.S. children under 18 are living in immigrant families (Turner, 2015). It is likely that by 2060, nearly 20% of the U.S. population will be foreign born, and people of Hispanic origin will comprise almost 30% of that population. By 2044, more than half of the U.S. population will be members of some minority group (Colby & Ortman, 2015).
- Almost 15 million children—about 22% of all children—live in poverty, defined in 2017 by the U.S. Department of Health and Human Services as an income of \$24,600

for a family of four (\$30,750 in Alaska and \$28,290 in Hawaii). And in the public schools, just over half the students qualify for free or reduced cost lunches—a rough indicator of poverty (Southern Education Foundation, 2015). At 22%, the United States has the *second highest* rate of child poverty among the 35 economically advantaged countries of the world, just above Romania and below Bulgaria. Iceland, the Scandinavian countries, Cyprus, and the Netherlands have the lowest rates of child poverty, about 7% or less (Ann E. Casey Foundation, 2015; Children’s Defense Fund, 2015; National Center for Child Poverty, 2013; UNICEF, 2012).

- The typical Black household has about 6% of the wealth of the typical White household. The figure for Hispanic households is 8% (Shin, 2015).
- About one in six American children have a mild-to-severe developmental disability such as speech and language impairments, intellectual disabilities, cerebral palsy, or autism. Over half of these children spend most or their time in general education classes (Centers for Disease Control, 2015c).
- In 2012, for children ages birth to 17, 20% had parents who were divorced or separated, 11% were living with someone who had an alcohol or drug problem, 7% had a parent who had served time in jail, and 9% lived with someone who was mentally ill (Child Trends, 2013).

Based on statistics such as these, Erica Turner (2015) concluded, “American society and schools are more diverse and more unequal than ever” (p. 4). In contrast, because of the effects of mass media, these diverse students share many similarities today, particularly the fact that most are far more technologically literate than their teachers. For example:

- Infants to 8-year-olds spend an average of almost 2 hours each day watching TV or videos, 29 minutes listening to music, and 25 minutes working with computers or

computer games. In 2013, 75% of homes with children under age 8 had a smartphone, tablet, or other mobile device (Common Sense Media, 2012, 2013b). Today the numbers probably have increased.

- According to a 2015 Pew Research survey, 92% of 13- to 17-year-olds said they went online daily, and 24% were online “almost constantly.” This is possible because 88% of teenagers have access to some kind of mobile phone and most of these (73%) are smartphones. And 71% of teens use more than one social media site; Facebook, Instagram, and Snapchat are the most popular (Lenhart, 2015).

These statistics are dramatic but a bit impersonal. As a teacher, counselor, recreational worker, speech therapist, or family member, you will encounter real children. In this book, you will meet many individuals such as Josué, a bright first grader whose first language is Spanish, struggling to care about learning read in a language that offers only, “run Spot, run”; Alex, an 11-year-old who has created 10 languages and 30 or 40 alphabets; Jamie Foxx, a very bright third-grade student in a small, Texas town whose teacher rewards him for working hard all week by letting him do stand-up comedy for the class on Fridays; Tracy, a failing high school student who does not understand why her study strategies are failing her; Felipe, a fifth-grade boy from a Spanish-speaking family who is working to learn school subjects and make friends in a language that is new to him; Ternice, an outspoken African American girl in an urban middle school who is hiding her giftedness; Trevor, a second-grade student who has trouble with the meaning of *symbol*; Allison, head of a popular clique and tormentor of the outcast Stephanie; Eliot, a bright sixth-grade student with severe learning disabilities; and Jessie, a student in a rural high school who just doesn’t seem to care about her sinking grade-point average (GPA) or school in general.

Even though students in classrooms are increasingly diverse in race, ethnicity, language, and economic level, teachers are much less diverse—the percentage of White teachers is increasing (now about 90%), while the percentage of Black teachers is falling, down to about 7%. Clearly, it is important for all teachers to know and be able to work effectively with all their students. Several chapters in this book are devoted to understanding these diverse students. In addition, many times within each chapter, we will explore student diversity and inclusion through research, cases, and practical applications.

Confidence in Every Context

Schools are about teaching and learning; all other activities are secondary. But teaching and learning in the contexts just described can be challenging for both teachers and students. This book is about understanding the complex processes of development, learning, motivation, teaching, and assessment so that you can become a capable and confident teacher.

Much of my own research has focused on **teachers’ sense of efficacy**, defined as a teacher’s belief that he or she can reach even difficult students to help them learn. This confident belief appears to be one of the few personal characteristics of teachers that predict student achievement (Çakıroğlu, Aydın, & Woolfolk Hoy, 2012; Woolfolk Hoy, Hoy, & Davis, 2009). Teachers with a high sense of efficacy work harder and persist longer even when students are difficult to teach, in part because these teachers believe in themselves and in their students. Also, they are less likely to experience burnout and more likely to be satisfied with their jobs (Fernet, Guay, Senécal, & Austin, 2012; Fives, Hamman, & Olivarez, 2005; Klassen & Chiu, 2010).

I have found that prospective teachers tend to increase in their personal sense of efficacy as a consequence of completing student teaching. But sense of efficacy may decline after the first year as a teacher, perhaps because the support that was provided during student teaching is gone (Woolfolk Hoy & Burke-Spero, 2005). Teachers’ sense of efficacy is higher in schools when the other teachers and administrators have high expectations for students and the teachers receive help from their principals in solving instructional and management problems (Capa, 2005). Efficacy grows from real success

Teachers’ sense of efficacy

A teacher’s belief that he or she can reach even the most difficult students and help them learn.

with students, not just from the moral support or cheerleading of professors and colleagues. Any experience or training that helps you succeed in the day-to-day tasks of teaching will give you a foundation for developing a sense of efficacy in your career. This book was written to provide the knowledge and skills that form a solid foundation for an authentic sense of efficacy in teaching.

High Expectations for Teachers and Students

In 2002, President George W. Bush signed into law the No Child Left Behind (NCLB) Act. Actually, NCLB was the latest authorization of the Elementary and Secondary Education Act (ESEA), first passed in 1965. In a nutshell, NCLB required that all students in grades 3 through 8 and once more in high school take annual standardized achievement tests in reading and mathematics. In addition, they had to be tested in science once in each grade span: elementary, middle, and high school. Based on these test scores, schools were judged to determine if their students were making adequate yearly progress (AYP) toward becoming proficient in the subjects tested. States and schools had to develop AYP goals and report scores separately for several subgroups, including racial and ethnic minority students, students with disabilities, students whose first language is not English, and students from low-income homes. But no matter how states defined these standards, NCLB required that all students reach proficiency by the end of the 2013–2014 school year. You probably noticed—this did not happen.

For a while, NCLB dominated education. Testing expanded. Schools and teachers were penalized if they did not perform. For example, if a school underperformed for 5 years, federal money could be taken away, teachers and principals could be fired, and schools could be converted to charter schools or closed. As you can imagine, or may have experienced yourself, such high-stakes penalties pushed teachers and schools to “teach to the test” or worse. The curriculum narrowed and much time was spent on drill and practice. Cheating was a problem and graduation requirements were dumbed down in some high schools to avoid receiving penalties (Davidson, Reback, Rockoff, & Schwartz 2015; Meens & Howe, 2015; Strauss, 2015).

With all this focus on test preparation, some schools and states seemed to make progress toward their AYP goals, but too many schools were labeled as failing. A closer look at these successes and failures showed that the states used very different formulas and procedures for calculating AYP, so we can’t really compare results across states (Davidson et al., 2015). All in all, NCLB requirements were widely criticized as “blunt instruments, generating inaccurate performance results, perverse incentives, and unintended negative consequences” (Hopkins et al., 2013, p. 101).

NCLB was supposed to be reauthorized in 2007 or 2008, but this process was not completed until December 10, 2015 when President Barack Obama signed the **Every Student Succeeds Act (ESSA)**. The main differences between ESSA and NCLB are that the requirement for proficiency for all students by a certain date has been dropped, most control is returned to the states to set standards and develop interventions, and penalties are no longer central to the law. A few key changes include:

1. Schools still must test the same subjects in the same grades, and at least 95% of students must participate in the testing. But the local districts now can decide when to test, whether to break one big test into several smaller tests, and even how to find better tests that really capture important student learning. Accountability plans have to be submitted to the Department of Education. In these plans, test scores and graduation rates have to be given greater weight than other more subjective measures, but at least one additional measure of school quality such as school climate and safety or student engagement must be included, along with measures of progress toward English language proficiency for English learners (Korte, 2015).
2. The schools still have to gather data about different subgroups of students, but they are not penalized if the students in these groups do not perform, unless the underperformance persists over time.

Every Student Succeeds Act (ESSA) The 2015 replacement for the No Child Left Behind Act. ESSA drops the requirement for proficiency for all students by a certain date has been dropped and returns most control to the states to set standards and develop interventions.

3. Only schools at the bottom 5% of test scores, schools that graduate less than two-thirds of their students, and schools where subgroups consistently underperform will be considered failing. The states must intervene in these schools with “evidence-based” programs, but ESSA leaves the decisions about which interventions to use to the state (Strauss, 2015).
4. States are allowed to adopt the Common Core Standards (see Chapter 14), but there are no federal incentives or pressures to do so. The goal is for high school graduates to be college and career ready.
5. States are now required to fund “equitable services” for children in private and religious schools if those students are eligible for special services. This could be a problem for many states that do not have enough money now to adequately fund these services in public schools (Strauss, 2015).
6. ESSA also emphasizes increased access to preschool by including new funding for early childhood education (Wong, 2015).

Even though these seem to be major changes, the actual effects for many states and schools may not be too dramatic. By 2015, the Secretary of Education had waived the requirement to reach 100% proficiency for 42 states and the District of Columbia. To get the waivers, the states had to show they had adopted their own testing and accountability programs and were making progress toward the goal of college or career readiness for all their graduates. In other words, these 42 states and the District of Columbia already were operating under the main provisions of ESSA (Meens & Howe, 2015; Wong, 2015).

One provision of the ESSA of interest to all teachers and teacher educators is a provision that establishes teacher education academies. The types of academies favored are nontraditional, non-university, and for-profit programs that don't have to meet the standards of university programs. Many teacher educators worry that this step will lower the quality of new teachers (Strauss, 2015).

Time will tell how the new ESSA law unfolds, especially with the election of Donald Trump as President. Many excellent teachers still believe they are spending too much time preparing for tests and not enough time supporting student learning in subjects not tested, such as social studies, art, music, physical education, and technology (Cusick, 2015). But no matter what policies the government adopts, capable and confident teachers will be required. Is that true? Do teachers really make a difference? Good question.

Do Teachers Make a Difference?

You saw in the statistics presented earlier that many American children are growing up in poverty. For a while, some researchers concluded that wealth and social status, not teaching, were the major factors determining who learned in schools (e.g., Coleman, 1966). In fact, much of the early research on teaching was conducted by educational psychologists who refused to accept these claims that teachers were powerless in the face of poverty and societal problems (Wittrock, 1986).

How can you decide whether teaching makes a difference? Perhaps one of your teachers influenced your decision to become an educator. Even if you had such a teacher, and I hope you did, one of the purposes of educational psychology in general and this text in particular is to go beyond individual experiences and testimonies, powerful as they are, to examine larger groups. The results of many large-group studies speak to the power of teachers in the lives of students, as you will see next.

TEACHER-STUDENT RELATIONSHIPS. Bridgett Hamre and Robert Pianta (2001) monitored all the children who entered kindergarten one year in a small school district and continued in that district through the eighth grade. The researchers concluded that the quality of the teacher-student relationship in kindergarten (defined in terms of level of conflict with the child, the child's dependency on the teacher, and the teacher's affection for the child) predicted a number of academic and behavioral outcomes *through the eighth grade*, particularly for students with many behavior problems.

MyLab Education Podcast 1.1

In this podcast, textbook author Anita Woolfolk talks about the importance of teachers in students' lives. Did you know that “teacher involvement and caring are the most significant predictors of a student's engagement in school from first grade through twelfth grade?” Listen to learn more.

MyLab Education Video Example 1.1

A bilingual teacher conducts a discussion with immigrant high school students. She asks students to discuss what teachers can do to help English learners and students from different cultures.

Even when the gender, ethnicity, cognitive ability, and behavior ratings of the student were accounted for, the relationship with the teacher still predicted aspects of school success. So students with significant behavior problems in the early years are less likely to have problems later in school if their first teachers are sensitive to their needs and provide frequent, consistent feedback.

It appears that the connection between teacher relationships and student outcomes is widespread. Deborah Roorda and her colleagues (2011) reviewed research from 99 studies around the world that examined the connections between teacher–student relationships and student engagement. Positive teacher relationships predicted positive student engagement at every grade, but the relationships were especially strong for students who were at risk academically and for older students. As an example, Russell Bishop and his colleagues (2014) observed 1,263 secondary teachers who taught the indigenous Maori students of New Zealand. The researchers found that when teachers established warm, caring relationships with their students, similar to those of an extended family, the students were more engaged. In fact, without such relationships there was no engagement. So evidence is mounting for a strong association between the quality of teacher–child relationships and school performance.

THE COST OF POOR TEACHING. In a widely publicized study, researchers examined how students are affected by having several effective or ineffective teachers in a row (Sanders & Rivers, 1996). They looked at fifth graders in two large metropolitan school systems in Tennessee. Students who had highly effective teachers for third, fourth, and fifth grades scored at the 83rd percentile on average on a standardized mathematics achievement test in one district and at the 96th percentile in the other (99th percentile is the highest possible score). In contrast, students who had the least effective teachers 3 years in a row averaged at the 29th percentile in math achievement in one district and 44th percentile in the other—a difference of over 50 percentile points in both cases! Students who had average teachers or a mixture of teachers with low, average, and high effectiveness for the 3 years had math scores between these extremes. Sanders and Rivers concluded that the best teachers encouraged good-to-excellent gains in achievement for all students, but lower-achieving students were the first to benefit from good teaching. The effects of teaching were cumulative and residual; that is, better teaching in a later grade could partially make up for less effective teaching in earlier grades, but could not erase all the deficits traced to poor teachers (Hanushek, Rivkin, & Kain, 2005; Rivkin, Hanushek, & Kain, 2001).

Another study about test score gains from the Los Angeles public schools may be especially interesting to you. Robert Gordon and his colleagues (2006) measured the test performance of elementary school students in *beginning teachers'* classes. Teachers were ranked into quartiles based on how well their students performed during the teachers' first 2 years. Then the researchers looked at the test performance of students in classes with the top 25% of the teachers and the bottom 25% during their third year of teaching. After controlling for the effects of students' prior test scores, their families' wealth, and other factors, they found that the students working with the top 25% of the teachers gained an average of 5 percentile points more compared to students with similar beginning of the year test scores, while students in the bottom 25% lost an average of 5 percentile points. If these losses accumulate, then students working with poorer teachers would fall farther and farther behind. In fact, the researchers speculated that “. . . having a top-quartile teacher four years in a row would be enough to close the black-white test score gap” [of about 34 percentile points] (R. Gordon, Kane, & Staiger, 2006, p. 8).

Effective teachers who establish positive relationships with their students appear to be a powerful force in those students' lives. Students who have problems seem to benefit the most from good teaching. So an important question is, “What makes a teacher effective? What is good teaching?”

WHAT IS GOOD TEACHING?

Educators, psychologists, philosophers, novelists, journalists, filmmakers, mathematicians, scientists, historians, policy makers, and parents, to name only a few groups, have examined this question; there are hundreds of answers. And good teaching is not confined to classrooms. It occurs in homes and hospitals, museums and sales meetings, therapists' offices, and summer camps. In this book we are primarily concerned with teaching in classrooms, but much of what you will learn applies to other settings as well.

Inside Three Classrooms

To begin our examination of good teaching, let's step inside the classrooms of three outstanding teachers. The three situations are real. The first two teachers worked with my student teachers in local elementary and middle schools and were studied by one of my colleagues, Carol Weinstein (Weinstein & Romano, 2015). The third teacher became an expert at helping students with severe learning difficulties, with the guidance of a consultant.

A BILINGUAL FIRST GRADE. Most of the 25 students in Viviana's class have recently emigrated from the Dominican Republic; the rest come from Nicaragua, Mexico, Puerto Rico, and Honduras. Even though the children speak little or no English when they begin school, by the time they leave in June, Viviana has helped them master the normal first-grade curriculum for their district. She accomplishes this by teaching in Spanish early in the year to aid understanding and then gradually introducing English as the students are ready. Viviana does not want her students segregated or labeled as disadvantaged. She encourages them to take pride in their Spanish-speaking heritage and uses every available opportunity to support their developing English proficiency.

Both Viviana's expectations for her students and her commitment to them are high. She has an optimism that reveals her dedication: "I always hope that there's somebody out there that I will reach and that I'll make a difference" (Weinstein & Romano, 2015, p. 15). For Viviana, teaching is not just a job; it is a way of life.

A SUBURBAN FIFTH GRADE. Ken teaches fifth grade in a suburban school in central New Jersey. Students in the class represent a range of racial, ethnic, family income, and language backgrounds. Ken emphasizes "process writing." His students complete first drafts, discuss them with others in the class, revise, edit, and "publish" their work. The students also keep daily journals and often use them to share personal concerns with Ken. They tell him of problems at home, fights, and fears; he always takes the time to respond in writing. Ken also uses technology to connect lessons to real life. Students learn about ocean ecosystems by using a special interactive software program. For social studies, the class plays two simulation games that focus on history. One is about coming of age in Native American cultures, and the other focuses on the colonization of America.

Throughout the year, Ken is very interested in the social and emotional development of his students; he wants them to learn about responsibility and fairness as well as science and social studies. This concern is evident in the way he develops his class rules at the beginning of the year. Rather than specifying do's and don'ts, Ken and his students devise a "Bill of Rights" for the class, describing the rights of the students. These rights cover most of the situations that might need a "rule."

AN INCLUSIVE CLASS. Eliot was bright and articulate. He easily memorized stories as a child, but he could not read by himself. His problems stemmed from severe learning difficulties with auditory and visual integration and long-term visual memory. When he tried to write, everything got jumbled. Dr. Nancy White worked with Eliot's teacher, Mia Russell, to tailor intensive tutoring that specifically focused on Eliot's individual learning patterns and his errors. With his teachers' help, over the next years, Eliot became an expert on his own learning and was transformed into an independent learner; he knew which strategies he had to use and when to use them. According to Eliot, "Learning that stuff is not fun, but it works!" (Hallahan & Kauffman, 2006, pp. 184–185).

Teacher Professionalism (IV, A2)

Begin your own development by reading educational publications. One widely read periodical is *Education Week*. You can access it online at edweek.com.

What do you see in these three classrooms? The teachers are confident and committed to their students. They must deal with a wide range of students: different languages, different home situations, and different abilities and learning challenges. They must adapt instruction and assessment to students' needs. They must make the most abstract concepts, such as ecosystems, real and understandable for their particular students. The whole time these experts are navigating through the academic material, they also are taking care of the emotional needs of their students, propping up sagging self-esteem, and encouraging responsibility. If we followed these teachers from the first day of class, we would see that they carefully plan and teach the basic procedures for living and learning in their classes. They can efficiently collect and correct homework, regroup students, give directions, distribute materials, and deal with disruptions—and do all of this while also making a mental note to find out why one of their students is so tired. Finally, they are **reflective**—they constantly think back over situations to analyze what they did and why, and to consider how they might improve learning for their students.

MyLab Education Video Example 1.2

Teachers must be both knowledgeable and inventive. They must be able to use a range of strategies, and they must also be capable of inventing new strategies. In this video, the teacher knows her students and uses strategies that help each student learn. Observe how she supports students who are English language learners, and observe her method of grouping students to meet diverse needs.

SO WHAT IS GOOD TEACHING? Is good teaching science or art: the application of research-based theories or the creative invention of specific practices? Is a good teacher an expert explainer—“a sage on the stage” or a great coach—“a guide by the side”? These debates have raged for years. In your other education classes, you probably will encounter criticisms of the scientific, teacher-centered sages. You will be encouraged to be inventive, student-centered guides. *But beware of either/or choices.* Teachers must be both knowledgeable and inventive. They must be able to use a range of strategies, and they must also be capable of inventing new strategies. They must have some basic research-based routines for managing classes, but they must also be willing and able to break from the routine when the situation calls for change. They must know the research on student development, and they also need to know their own particular students who are unique combinations of culture, gender, and geography. Personally, I hope you all become teachers who are both sages and guides, wherever you stand.

Another answer to “What is good teaching?” involves considering what different models and frameworks for teaching have to offer. We look at this next.

MODELS OF GOOD TEACHING: TEACHER OBSERVATION AND EVALUATION. In the last few years, educators, policy makers, government agencies, and philanthropists have spent millions of dollars identifying what works in teaching and specifically how to identify good teaching. These efforts have led to a number of models for teaching and teacher evaluation systems. We will briefly examine three to help answer the question, “What is good teaching?” Another reason to consider these models is that when you become a teacher, you may be evaluated based on one of these approaches, or something like them—teacher evaluation is a very hot topic these days! We will look at Charlotte Danielson’s Framework for Teaching, the high-leverage practices identified by TeachingWorks at the University of Michigan, and the Measures of Effective Teaching project sponsored by the Bill and Melinda Gates Foundation.

Danielson’s Framework for Teaching. The *Framework for Teaching* was first published in 1996 and has been revised three times since then, the latest in 2013 (see danielsongroup.org for information about Charlotte Danielson and the *Framework for Teaching*). According to Charlotte Danielson (2013):

The Framework for Teaching identifies those aspects of a teacher’s responsibilities that have been documented through empirical studies and theoretical research as promoting improved student learning. While the Framework is not the only possible description of practice, these responsibilities seek to define what teachers should know and be able to do in the exercise of their profession. (p. 3)

Danielson’s Framework has 4 domains or areas of responsibility: *Planning and Preparation*, *Classroom Environment*, *Instruction*, and *Professional Responsibilities*. Each domain is further divided into 5 or 6 components, making a total of 22 components for the

Reflective Thoughtful and inventive. Reflective teachers think back over situations to analyze what they did and why, and to consider how they might improve learning for their students.

entire framework. For example, Domain 1: Planning and Preparation, is divided into 6 components:

- 1a Demonstrating knowledge of content and pedagogy
- 1b Demonstrating knowledge of students
- 1c Setting instructional objectives
- 1d Demonstrating knowledge of resources
- 1e Designing coherent instruction
- 1f Designing student assessments

When the Framework is used for teacher evaluation, each of these 22 components is further divided into elements (76 in all), and several indicators are specified for each component. For example, component 1b, demonstrating knowledge of students, includes the elements describing knowledge of

- child and adolescent development
- the learning process
- students' skills, knowledge, and language proficiency
- students' interests and cultural heritage
- students' special needs

Indicators of this knowledge of students include the formal and informal information about students that the teacher gathers when planning instruction, the students' interests and needs the teacher identifies, the teacher's participation in community cultural events, opportunities the teacher has designed for families to share their cultural heritages, and any databases the teacher has for students with special needs (Danielson, 2013).

The evaluation system further defines four levels of proficiency for each of the 22 components: unsatisfactory, basic, proficient, and distinguished, with a definition, critical attributes, and possible examples of what each level might look like in action. Two examples of distinguished knowledge of students are a teacher who plans lessons with three different follow-up activities designed to match different students' abilities and a teacher who attends a local Mexican heritage event to meet members of her students' extended families. Many other examples are possible, but these two give a sense of distinguished knowledge of students (component 1b).

You can see that it would take extensive training to use this framework well for teacher evaluation. When you become a teacher, you may learn more about this conception of good teaching because your school district is using it. For now, be assured that you will gain knowledge and skills in all 22 components in this text. For example, you will gain knowledge of students (component 1b) in Chapters 2 through 6.

TeachingWorks. TeachingWorks is a national project based at the University of Michigan and dedicated to improving teaching practice. Project members working with experienced teachers have identified 19 high-leverage teaching practices, defined as actions that are central to teaching and useful across most grade levels, academic subjects, and teaching situations. The TeachingWorks researchers call these practices “a set of ‘best bets,’ warranted by research evidence, wisdom of practice, and logic” (teachingworks.org/work-of-teaching/high-leverage-practices). These practices are specific enough to be taught and observed, so they can be a basis for teacher learning and evaluation. See Table 1.1 on the next page for these 19 practices. Again, you will develop skills and knowledge about all of these practices in this text. (For a more complete description of the 19 high-leverage practices, see teachingworks.org/work-of-teaching/high-leverage-practices.)

When you compare the high-leverage practices in Table 1.1 with the Danielson components listed earlier, do you see similarities and overlaps?

Measures of Teacher Effectiveness. In 2009, the Bill and Melinda Gates Foundation launched the Measures of Teaching Effectiveness (MET) Project, a research partnership between 3,000 teachers and research teams at dozens of institutions. The goal was clear from the title—to build and test measures of effective teaching. The Gates Foundation

TABLE 1.1 • TeachingWorks 19 High-Leverage Teaching Practices

These practices are based on research evidence, the wisdom of practice, and logic.

1. Making content (e.g., specific texts, problems, theories, processes) explicit through explanation, modeling, representations, and examples
2. Leading a whole-class discussion
3. Eliciting and interpreting individual students' thinking
4. Establishing norms and routines for classroom discourse and work that are central to the subject-matter domain
5. Recognizing particular common patterns of student thinking and development in a subject-matter domain
6. Identifying and implementing an instructional response or strategy in response to common patterns of student thinking
7. Teaching a lesson or segment of instruction
8. Implementing organizational routines, procedures, and strategies to support a learning environment
9. Setting up and managing small group work
10. Engaging in strategic relationship-building conversations with student
11. Setting long- and short-term learning goals for students referenced to external benchmarks
12. Appraising, choosing, and modifying tasks and texts for a specific learning goal
13. Designing a sequence of lessons toward a specific learning goal
14. Selecting and using particular methods to check understanding and monitor student learning during and across lessons
15. Composing, selecting, and interpreting and using information from quizzes, tests and other methods of summative assessment
16. Providing oral and written feedback to students on their work
17. Communicating about a student with a parent or guardian
18. Analyzing instruction for the purpose of improving it
19. Communicating with other professionals

Source: Reprinted with permission from TeachingWorks (2014), *High-leverage practices*. Retrieved from <http://www.teachingworks.org/work-of-teaching/high-leverage-practices>

tackled this problem because research shows that teachers matter; they matter more than technology or funding or school facilities. In pursuing the goal, the project members made a key assumption. Teaching is complex; multiple measures will be needed to capture effective teaching and provide useful feedback for personnel decisions and professional development. In addition to using student achievement gains on state tests, the MET researchers examined many established and newer measures of effectiveness and content knowledge. The final report of the project (MET Project, 2013) identified the following three measures that are used together as a valid and reliable way of assessing teaching that leads to student learning:

1. Student *gains on state tests*.
2. Surveys of *student perceptions* of their teachers based on the Tripod Student Perception Survey developed by Ron Ferguson at Harvard University (R. F. Ferguson, 2008). This survey asks students to agree or disagree with statements such as “My teacher takes time to help us remember what we learn” (for K–2 students); “In class we learn to correct our mistakes (upper elementary students); and “In this class, my teacher accepts nothing less than our full effort” (secondary students) (from Cambridge Education, Tripod Project, Student Survey System).
3. *Classroom observations* from the Danielson (2013) Framework for Teaching.

Remember, teaching is complex. To capture effective teaching, these measures have to be used accurately and together. Also, in both state tests and tests of higher-level thinking, the best combination of reliability and prediction of student gains comes when gains on standardized tests are weighted between 33% and 50% in assessing effectiveness, with student perception and class observation results providing the rest of the information (MET Project, 2013).

Are you surprised that evaluating a teacher's content knowledge for the subject taught did not make the cut in measuring teacher effectiveness? So far, math seems to be the one area where teacher knowledge is related to student learning, but with better

measures of teacher knowledge, we may find more relationships (Gess-Newsome, 2013; Goe, 2013; MET Project, 2013).

Is all this talk about expert teachers and effective teaching making you a little nervous? Viviana, Ken, and Mia are experts at the science and art of teaching, but they have years of experience. What about you?

Beginning Teachers

STOP & THINK Imagine walking into your first day of teaching. List the concerns, fears, and worries you have. What assets do you bring to the job? What would build your confidence to teach? •

Beginning teachers everywhere share many concerns, including maintaining classroom discipline, motivating students, accommodating differences among students, evaluating students' work, dealing with parents, and getting along with other teachers (Conway & Clark, 2003; Melnick & Meister, 2008; Veenman, 1984). Many teachers also experience what has been called “reality shock” when they take their first job because they really cannot ease into their responsibilities. On the first day of their first job, beginning teachers face the same tasks as teachers with years of experience. Student teaching, while a critical element, does not really prepare prospective teachers for starting off a school year with a new class. If you listed any of these concerns in your response to the *Stop & Think* question, you shouldn't be troubled. They come with the job of being a beginning teacher (Borko & Putnam, 1996; Cooke & Pang, 1991).

With experience, hard work, and good support, seasoned teachers can focus on the students' needs and judge their success by their students' accomplishments (Fuller, 1969; Pigge & Marso, 1997). One experienced teacher described the shift from concerns about yourself to concerns about your students in this way: “The difference between a beginning teacher and an experienced one is that the beginning teacher asks, ‘How am I doing?’ and the experienced teacher asks, ‘How are the children doing?’” (Codell, 2001, p. 191).

My goal in writing this book is to give you the foundation for becoming an expert as you gain experience. One thing experts do is listen to their students. Table 1.2 shows some advice a first-grade class gave to their student teacher: It looks like the students know about good teaching, too.

TABLE 1.2 • Advice for Student Teachers from Their Students

The students in Ms. Amato's first-grade class gave this advice as a gift to their student teacher on her last day.

1. Teach us as much as you can.
2. Give us homework.
3. Help us when we have problems with our work.
4. Help us to do the right thing.
5. Help us make a family in school.
6. Read books to us.
7. Teach us to read.
8. Help us write about faraway places.
9. Give us lots of compliments, like “Oh, that's so beautiful.”
10. Smile at us.
11. Take us for walks and on trips.
12. Respect us.
13. Help us get our education.

I began this chapter claiming that educational psychology is the one of the most important courses you will take. OK, maybe I am a bit biased—I have been teaching the subject for over four decades! So let me tell you more about my favorite topic.

Connect and Extend to PRAXIS II®

Teacher Professionalism (IV, A1)

Your professional growth relies on your becoming a member of a community of practice. The national organizations listed here have hundreds of affiliations and chapters across the country with regular conferences, conventions, and meetings to advance instruction in their areas. Take a look at their Web sites to get a feel for their approaches to issues related to professionalism.

- National Council of Teachers of English (ncte.org)
- International Reading Association (reading.org)
- National Science Teachers Association (nsta.org)
- National Council for the Social Studies (ncss.org)
- National Council of Teachers of Mathematics (nctm.org)

THE ROLE OF EDUCATIONAL PSYCHOLOGY

For as long as the formal study of educational psychology has existed—over 100 years—there have been debates about what it really is. Some people believe educational psychology is simply knowledge gained from psychology and applied to the activities of the classroom. Others believe it involves applying the methods of psychology to study classroom and school life (Brophy, 2003). A quick look at history shows that educational psychology and teaching have been closely linked since the beginning.

In the Beginning: Linking Educational Psychology and Teaching

In one sense, educational psychology is very old. Issues Plato and Aristotle discussed—the role of the teacher, the relationship between teacher and student, methods of teaching, the nature and order of learning, the role of emotion in learning—are still topics in educational psychology today. But let's fast forward to recent history. From the beginning, psychology in the United States was linked to teaching. At Harvard in 1890, William James founded the field of psychology and developed a lecture series for teachers entitled *Talks to Teachers about Psychology*. These lectures were given in summer schools for teachers around the country and then published in 1899. James's student, G. Stanley Hall, founded the American Psychological Association. Teachers helped him collect data for his dissertation about children's understandings of the world. Hall encouraged teachers to make detailed observations to study their students' development—as his mother had done when she was a teacher. Hall's student John Dewey founded the Laboratory School at the University of Chicago and is considered the father of the progressive education movement (Berliner, 2006; Hilgard, 1996; Pajares, 2003). Another of William James's students, E. L. Thorndike, wrote the first educational psychology text in 1903 and founded the *Journal of Educational Psychology* in 1910.

Educational Psychology Today

What is educational psychology today? The view generally accepted is that **educational psychology** is a distinct discipline with its own theories, research methods, problems, and techniques. Educational psychologists do research on learning and teaching and, at the same time, work to improve educational policy and practice (Anderman, 2011). To understand as much as possible about learning and teaching, educational psychologists examine what happens when someone (a teacher or parent or software designer) teaches something (math or weaving or dancing) to someone else (student or co-worker or team) in some setting (classroom or theater or gym) (Berliner, 2006; Schwab, 1973). So educational psychologists study child and adolescent development; learning and motivation—including how people learn different academic subjects such as reading or mathematics; social and cultural influences on learning; teaching and teachers; and assessment, including testing (Alexander & Winne, 2006).

But even with all this research on so many topics, are the findings of educational psychologists really that helpful for teachers? After all, most teaching is just common sense, isn't it? Let's take a few minutes to examine these questions.

Is It Just Common Sense?

In many cases, the principles set forth by educational psychologists—after spending much thought, time, and money for research—sound pathetically obvious. People are tempted to say, and usually do say, "Everyone knows that!" Consider these examples.

Educational psychology

The discipline concerned with teaching and learning processes; applies the methods and theories of psychology and has its own as well.

HELPING STUDENTS. When should teachers provide help for lower-achieving students as they do class work?

Commonsense Answer. Teachers should offer help often. After all, these lower-achieving students may not know when they need help or they may be too embarrassed to ask for help.

ANSWER BASED ON RESEARCH. Sandra Graham (1996) found that when teachers provide help before students ask, the students and others watching are more likely to conclude that the student who was given assistance does not have the ability to succeed. The student is more likely to attribute failures to lack of ability instead of lack of effort, so motivation suffers.

SKIPPING GRADES. Should a school encourage exceptionally bright students to skip grades or to enter college early?

Commonsense Answer. No! Very intelligent students who are several years younger than their classmates are likely to be social misfits. They are neither physically nor emotionally ready for dealing with older students and would be miserable in the social situations that are so important in school, especially in the later grades.

ANSWER BASED ON RESEARCH. Maybe. The first two conclusions in the report *A Nation Deceived: How Schools Hold Back America's Brightest Children* are: (1) Acceleration is the most effective curriculum intervention for children who are gifted, and (2) for students who are bright, acceleration has long-term beneficial effects, both academically and socially (Colangelo, Assouline, & Gross, 2004). One example of positive long-term effects is that mathematically talented students who skipped grades in elementary or secondary school were more likely to go on to earn advanced degrees and publish widely cited articles in scientific journals (Park, Lubinski, & Benbow, 2013). Whether acceleration is the best solution for a student depends on many specific individual characteristics, including the intelligence and maturity of the student as well as the other available options. For some students, moving quickly through the material and working in advanced courses with older students can be a very positive experience (Kretschmann, Vock, & Lüdtke, 2014). See Chapter 4 for more on adapting teaching to students' abilities.

STUDENTS IN CONTROL. Does giving students more control over their own learning—more choices—help them learn?

Commonsense Answer. Of course! Students who choose their own learning materials and tasks will be more engaged and thus learn more.

ANSWER BASED ON RESEARCH. Not so fast! Sometimes giving students more control and choice can support learning, but many times it does not. For example, giving lower-ability students choice in learning tasks sometimes means the students just keep practicing what they already do well instead of tackling tougher assignments. This happened when hairdressing students were given choices. The lower-ability students kept practicing easy tasks such as washing hair but were reluctant to try more difficult projects such as giving permanents. When they developed portfolios to monitor their progress and received regular coaching and advice from their teachers, the students made better choices—so guided choice and some teacher control may be useful in some situations (Kicken, Brand-Gruwel, van Merriënboer, & Slot, 2009).

OBVIOUS ANSWERS? Years ago, Lily Wong (1987) demonstrated that just seeing research results in writing can make them seem obvious. She selected 12 findings from research on teaching. She presented 6 of the findings in their correct form and 6 in exactly the opposite form to both college students and experienced teachers. Both the college students and the teachers rated about half of the wrong findings as “obviously” correct.

Recently, Paul Kirschner and Joren van Merriënboer (2013) made a similar point when they challenged several “urban legends” in education about the assertion that learners (like the hairdressing students just described) know best how to learn. These current, strongly held beliefs about students as self-educating digital natives who can multitask, have unique learning styles, and always make good choices about how to learn *have no strong basis in research*, but they are embraced nonetheless.

You may have thought that educational psychologists spend their time discovering the obvious. The preceding examples point out the danger of this kind of thinking. When a principle is stated in simple terms, it can sound simplistic. A similar phenomenon takes place when we see a professional dancer or athlete perform; the well-trained performer makes it look easy. But we see only the results of the training, not all the work that went into mastering the individual movements. And bear in mind that any research finding—or its opposite—may sound like common sense. The issue is not what *sounds* sensible, but what is *demonstrated* when the principle is put to the test in research—our next topic (Gage, 1991).

Using Research to Understand and Improve Learning

STOP & THINK Quickly, list all the different research methods you can think of. •

Educational psychologists design and conduct many different kinds of research studies. Some of these are **descriptive studies**—their purpose is simply to describe events in a particular situation.

CORRELATION STUDIES. Often, the results of descriptive studies include reports of correlations. You will encounter many correlations in the coming chapters, so let's take a minute to examine this concept. A **correlation** is a number that indicates both the strength and the direction of a relationship between two events or measurements. Correlations range from +1.00 to −1.00. The closer the correlation is to either +1.00 or −1.00, the stronger the relationship. For example, the correlation between adult weight and height is about .70 (a strong relationship); the correlation between adult weight and number of languages spoken is about .00 (no relationship at all).

The sign of the correlation tells the direction of the relationship. A **positive correlation** indicates that the two factors increase or decrease together. As one gets larger, so does the other. Weight and height are positively correlated because greater weight tends to be associated with greater height. A **negative correlation** means that *increases* in one factor are related to *decreases* in the other, for example, the less you pay for a theater or concert ticket, the greater your distance from the stage. It is important to note that correlations do not prove cause and effect (see Figure 1.1). For example, weight and

Descriptive studies

Studies that collect detailed information about specific situations, often using observation, surveys, interviews, recordings, or a combination of these methods.

Correlations Statistical descriptions of how closely two variables are related.

Positive correlation A relationship between two variables in which the two increase or decrease together. Example: calorie intake and weight gain.

Negative correlation A relationship between two variables in which a high value on one is associated with a low value on the other. Example: height and distance from top of head to the ceiling.

FIGURE 1.1

CORRELATIONS DO NOT SHOW CAUSATION

When research shows that landscaped lawns and school achievement are correlated, it does not show causation. Community wealth, a third variable, may be the cause of both school achievement and landscaped lawns.

height are correlated—but gaining weight obviously does not *cause* you to grow taller. Knowing a person's weight simply allows you to make a general prediction about that person's height. Educational psychologists identify correlations so they can make predictions about important events in the classroom.

EXPERIMENTAL STUDIES. A second type of research—**experimentation**—allows educational psychologists to go beyond predictions and actually study cause and effect. Instead of just observing and describing an existing situation, the investigators introduce changes and note the results. First, a number of comparable groups of participants are created. In psychological research, the term **participants** (also called **subjects**) generally refers to the people being studied—such as teachers or ninth graders. One common way to make sure that groups of participants are essentially the same is to assign each person to a group using a random procedure. **Random** means each participant has an equal chance of being in any group. **Quasi-experimental studies** meet most of the criteria for true experiments, with the important exception that the participants are not assigned to groups at random. Instead, existing groups such as classes or schools participate in the experiments.

In experiments or quasi-experiments, for one or more of the groups studied, the experimenters change some aspect of the situation to see if this change or “treatment” has an expected effect. The results in each group are then compared, often using statistics. When differences are described as **statistically significant**, it means that they probably did not happen simply by chance. For example, if you see $p < .05$ in a study, this indicates that the result reported could happen by chance less than 5 times out of 100, and $p < .01$ means less than 1 time in 100.

A number of the studies we will examine attempt to identify cause-and-effect relationships by asking questions such as this: If some teachers receive training in how to teach spelling using word parts (*cause*), will their students become better spellers than students whose teachers did not receive training (*effect*)? This actually was a *field experiment* because it took place in real classrooms and not in a simulated laboratory situation. In addition, it was a *quasi-experiment* because the students were in existing classes and had not been randomly assigned to teachers, so we cannot be certain the experimental and control groups were the same before the teachers received their training. The researchers handled this by looking at improvement in spelling, not just final achievement level, and the results showed that the training worked (Hurry et al., 2005).

ABAB EXPERIMENTAL DESIGNS. The goal of ABAB designs is to determine the effects of a therapy, teaching method, or other intervention by first observing the participants for a baseline period (A) and assess the behavior of interest; then trying an intervention (B) and noting the results; then removing the intervention and go back to baseline conditions (A); and finally reinstating the intervention (B). This form of design can help establish a cause-and-effect relationship (Plavnick & Ferreri, 2013). For example, a teacher might record how much time students are out of their seats without permission during a weeklong baseline period (A). The teacher then tries ignoring those who are out of their seats, but praises those who are seated, again recording how many are wandering out of their seats for the week (B). Next, the teacher returns to baseline conditions (A) and records results, and then reinstates the praise-and-ignore strategy (B). When this intervention was first tested, the praise-and-ignore strategy proved effective in increasing the time students spent in their seats (C. H. Madsen, Becker, Thomas, Koser, & Plager, 1968).

CLINICAL INTERVIEWS AND CASE STUDIES. Jean Piaget pioneered an approach called the *clinical interview* to understand children's thinking. The clinical interview uses open-ended questioning to probe responses and to follow up on answers. Questions go wherever the child's responses lead. Here is an example of a clinical interview with a 7-year-old. Piaget is trying to understand the child's thinking about lies and truth, so he asks, “What is a lie?”

Experimentation Research method in which variables are manipulated and the effects recorded.

Participants/subjects People or animals studied.

Random Without any definite pattern; following no rule.

Quasi-experimental studies Studies that fit most of the criteria for true experiments, with the important exception that the participants are not assigned to groups at random. Instead, existing groups such as classes or schools participate in the experiments.

Statistically significant Not likely to be a chance occurrence.

What is a lie?—*What isn't true. What they say that they haven't done.*—Guess how old I am.—*Twenty.* No, I'm thirty.—Was that a lie you told me?—*I didn't do it on purpose.*—I know. But is it a lie all the same, or not?—*Yes, it is the same, because I didn't say how old you were.*—Is it a lie?—*Yes, because I didn't speak the truth.*—Ought you be punished?—*No.*—Was it naughty or not naughty?—*Not so naughty.*—Why?—*Because I spoke the truth afterwards!* (Piaget, 1965, p. 144)

Researchers also may employ case studies. A **case study** investigates one person or situation in depth. For example, Benjamin Bloom and his colleagues conducted in-depth studies of highly accomplished concert pianists, sculptors, Olympic swimmers, tennis players, mathematicians, and neurologists to try to understand what factors supported the development of outstanding talent. The researchers interviewed family members, teachers, friends, and coaches to build an extensive case study of each of these highly accomplished individuals (B. S. Bloom et al., 1985). Some educators recommend case study methods to identify students for gifted programs because the information gathered is richer than just test scores.

Case study Intensive study of one person or one situation.

Ethnography A descriptive approach to research that focuses on life within a group and tries to understand the meaning of events to the people involved.

Participant observation A method for conducting descriptive research in which the researcher becomes a participant in the situation in order to better understand life in that group.

Microgenetic studies Detailed observation and analysis of changes in a cognitive process as the process unfolds over a several-day or several-week period of time.

Qualitative research Exploratory research that attempts to understand the meaning of events to the participants involved using such methods as case studies, interviews, ethnography, participant observation, and other approaches that focus on a few people in depth.

Quantitative research Research that studies many participants in a more formal and controlled way using objective measures such as experimentation, statistical analyses, tests, and structured observations.

ETHNOGRAPHY. Ethnographic methods, borrowed from anthropology, involve studying the naturally occurring events in the life of a group to understand the meaning of these events to the people involved. In educational psychology research, ethnographies might study how students from different cultural groups are viewed by their peers or how teachers' beliefs about students' abilities affect classroom interactions. In some studies the researcher uses **participant observation**, actually participating in the group, to understand the actions from the perspectives of the people in the situation. Teachers can do their own informal ethnographies to understand life in their classrooms.

THE ROLE OF TIME IN RESEARCH. Many things that psychologists want to study, such as cognitive development (Chapter 2), happen over several months or years. Ideally, researchers would study the development by observing their subjects over many years as changes occur. These are called *longitudinal studies*. They are informative, but time-consuming, expensive, and not always practical: Keeping up with participants over a number of years as they grow up and move can be impossible. As a consequence, much research is *cross-sectional*, focusing on groups of students at different ages. For example, to study how children's conceptions of numbers change from ages 3 to 16, researchers can interview children of several different ages, rather than following the same children for 14 years.

Longitudinal studies and cross-sectional research examine change over long periods of time. The goal of **microgenetic studies** is to intensively study cognitive processes while the change is actually occurring. For example, researchers might analyze how children learn a particular strategy for adding two-digit numbers over the course of several weeks. The microgenetic approach has three basic characteristics: The researchers (a) observe the entire period of the change—from when it starts to the time it is relatively stable; (b) make many observations, often using video recordings, interviews, and transcriptions of the exact words of the individuals being studied; and (c) put the observed behavior “under a microscope,” that is, they examine it moment by moment or trial by trial. The goal is to explain the underlying mechanisms of change—for example, what new knowledge or skills are developing to allow change to take place. This kind of research is expensive and time-consuming, so often only one or two children are studied.

WHAT'S THE EVIDENCE? QUANTITATIVE VERSUS QUALITATIVE RESEARCH. There is a distinction you will encounter in your journey through educational psychology: the contrast between **qualitative research** and **quantitative research**. These are large categories, and like many categories, a bit fuzzy at the edges, but here are some simplified differences.

Qualitative Research. Case studies and ethnographies are examples of qualitative research. This type of research uses words, dialogue, events, themes, and images as data.

Interviews, observations, and analysis of transcripts are key procedures. The goal is to explore specific situations or people in depth and to understand the meaning of the events to the people involved in order to tell *their* story. Qualitative researchers assume that no process of understanding meaning can be completely objective. They are more interested in interpreting subjective, personal, or socially constructed meanings.

Quantitative Research. Both correlational and experimental types of research generally are quantitative because measurements are taken and computations are made. Quantitative research uses numbers, measurement, and statistics to assess levels or sizes of relationships among variables or differences between groups. Quantitative researchers try to be as objective as possible in order to remove their own biases from their results. One advantage of good quantitative research is that results from one study can be generalized or applied to other similar situations or people.

MIXED METHODS RESEARCH. Many researchers now are using *mixed methods* or *complementary methods* to study questions both broadly and deeply. These research designs are procedures for “collecting, analyzing, and ‘mixing’ both quantitative and qualitative methods in a single study or series of studies to understand a research problem” (Creswell, 2015, p. 537). There are three basic ways of combining methods. First, a researcher collects both quantitative and qualitative data at the same time, then merges and integrates the data in the analyses. In the second approach, the researcher collects quantitative data first, for example, from surveys or observation instruments, and then follows this by performing in-depth qualitative interviews of selected participants. Often the goal here is to explain or look for causes. Finally, the sequence can be reversed—the researcher first conducts interviews or case studies to identify research questions, then collects quantitative data as guided by the qualitative findings. Here the goal may be to explore a situation deeply (Creswell, 2015). Mixed methods research is becoming more common in educational psychology.

SCIENTIFICALLY BASED RESEARCH AND EVIDENCE-BASED PRACTICES. A requirement of the landmark 2002 NCLB Act was that educational programs and practices receiving federal money had to be consistent with “*scientifically based research*,” that is, rigorous systematic research that gathers valid and reliable data and analyzes those data with appropriate statistical methods. The 2015 Every Student Succeeds Act that replaced NCLB also requires “*evidence-based*” interventions in failing schools—strategies grounded in rigorous scientifically based research. For example, the U.S. Institute of Education Sciences (IES) provides a series of *Practice Guides* that contain recommendations from experts about various challenges educators face—guides to action based on strong evidence from research (http://ies.ed.gov/ncee/wwc/Publications_Reviews.aspx). In the upcoming chapters we will explore several of these guides, for example, *Organizing Instruction and Study to Improve Student Learning* in Chapter 8 (Pashler et al., 2007).

Scientifically based research and evidence-based practices fit the quantitative experimental approach described earlier better than qualitative methods such as ethnographic research or case studies, but there is continuing debate about what this means, as you will see in the *Point/Counterpoint* on the next page.

In the final analysis, the methods used—quantitative, qualitative, or a mixture of both—should fit the questions asked. Different approaches to research can ask different questions and provide different kinds of answers, as you can see in Table 1.3, on page 49.

TEACHERS AS RESEARCHERS. Research also can be a way to improve teaching in one classroom or one school. The same kind of careful observation, intervention, data gathering, and analysis that occurs in large research projects can be applied in any classroom to answer questions such as “Which writing prompts seem to encourage the most creative writing in my class?” “When does Kenyon seem to have the greatest difficulty concentrating on academic tasks?” “Would assigning task roles in science groups lead to more equitable participation of girls and boys in the work?” This kind of problem-solving

POINT/COUNTERPOINT: What Kind of Research Should Guide Education?

During the past decade, policies in both health care and the treatment of psychological problems have emphasized evidence-based practices (McHugh & Barlow, 2010). Is this right for education?

POINT ▶ **Yes, research should be scientific; educational reforms should be based on solid evidence.** According to Robert Slavin (2002), tremendous progress has taken place in fields such as medicine, agriculture, transportation, and technology because these fields base their practices on scientific evidence. Randomized clinical trials and replicated experiments are the sources of the evidence:

These innovations have transformed the world. Yet education has failed to embrace this dynamic, and as a result, education moves from fad to fad. Educational practice does change over time, but the change process more resembles the pendulum swings of taste characteristic of art or fashion (think hemlines) rather than the progressive improvements characteristic of science and technology. (2002, p. 16)

In his Presidential Address to the First Conference of the International Mind, Brain, and Education Society, Kurt Fischer (2009, pp. 3–4) made a similar point:

What happened to education? If research produces useful knowledge for most of the industries and businesses of the world, then shouldn't it be serving the same function for education? Somehow education has been mostly exempt from this grounding in research. . . . There is no infrastructure in education that routinely studies learning and teaching to assess effectiveness. If Revlon and Toyota can spend millions on research to create better products, how can schools continue to use alleged "best practices" without collecting evidence about what really works?

An article in the *New York Times* suggests lack of evidence is still a problem.

Most [educational] programs that had been sold as effective had no good evidence behind them. And when rigorous studies were done, as many as 90 percent of programs that seemed promising in small, unscientific studies had no effect on achievement or actually made achievement scores worse (Kolata, 2013, p. 3).

COUNTERPOINT ▶ **Experiments and controlled studies are not the only or even the best source of evidence for education.** David Olson (2004) disagrees strongly with Slavin's position. He claims that we cannot use medicine as an analogy to education. "Treatments" in education are much more complex and unpredictable than administering one drug or another in medicine. And every educational program is changed by classroom conditions and the way it is implemented. Patti Lather, a colleague of mine at Ohio State, says, "In improving the quality of practice, complexity and the messiness of practice-in-context cannot be fantasized away. To try to do so yields impoverishment rather than improvement. That loss is being borne by the children, teachers, and administrators in our schools" (Lather, 2004, p. 30). David Berliner (2002) makes a similar point:

Doing science and implementing scientific findings are so difficult in education because humans in schools are embedded in complex and changing networks of social interaction. The participants in those networks have variable power to affect each other from day to day, and the ordinary events of life (a sick child, a messy divorce, . . . a birthday party, alcohol abuse, a new principal, a new child in the classroom, rain that keeps the children from a recess outside the school building) all affect doing science in school settings by limiting the generalizability of educational research findings. Compared to designing bridges and circuits or splitting either atoms or genes, the science to help change schools and classrooms is harder to do because context cannot be controlled. (p. 19)

Berliner concludes, "A single method is not what the government should be promoting for educational researchers" (Berliner, 2002, p. 20). Some current proponents of evidence-based interventions in education suggest that we benefit from the knowledge and wisdom of both practitioners and researchers. **Design-based research** does just that. Practitioners identify research questions based on problems of practice. Researchers then bring their time and talent to gather and analyze the data to address those problems (Scanlan, 2015).

Beware Of Either/Or. Complex problems in education require a whole range of methods for study as well as input from both researchers and educators. *Qualitative* research tells us specifically what happened in one or a few situations. Conclusions can be applied deeply, but only to the issue that was studied. *Quantitative* research can tell us what generally happens under certain conditions. Conclusions can be applied more broadly. Educators must help researchers target the most important problems that need evidence-based solutions.

TABLE 1.3 • What Can We Learn?

Different approaches to research can ask and answer different questions.

RESEARCH METHOD	PURPOSES/QUESTIONS ADDRESSED	EXAMPLE
Correlational	To assess the strength and direction of the relation between two variables; to make predictions.	Is the average amount of homework completed weekly related to student performance on unit tests? If so, is the relation positive or negative?
Experimental	To identify cause-and-effect relations; to test possible explanations for effects.	Will giving more homework cause students to learn more in science class?
ABAB Experiment	To identify the effects of a treatment or intervention for one or more individuals.	When students record the number of pages they read each night, will they read more pages? If they stop recording, will their amount of reading return to the previous levels?
Case Studies	To understand one or a few individuals or situations in depth.	How does one boy make the transition from a small rural elementary school to a large middle school? What are his main problems, concerns, issues, accomplishments, fears, supports, etc.?
Ethnography	To understand experiences from the participants' point of view: What is their meaning?	How do new teachers make sense of the norms, expectations, and culture of their new school, and how do they respond?
Mixed Methods	To ask complex questions involving causes, meanings, and relations among variables; to pursue both depth and breadth in research questions.	Based on a study of 20 classrooms using quantitative observational instruments, select the 5 classes with the fewest behavior problems and the 5 with the most problems late in the year. Next interview those teachers and their students and analyze videotapes made the first weeks of school to answer the question: Did the effective and ineffective teachers differ in how they established rules and procedures in their classes?

investigation is called **action research**. By focusing on a specific problem and making careful observations, teachers can learn a great deal about both their teaching and their students.

You can find reports of the findings from all types of studies in journals that are referenced in this book. For years I was editor of the *Theory Into Practice* journal (tip.ehe.osu.edu). I think this is a terrific journal to inspire and guide action research in classrooms. For a great overview of the past 50 years in educational research and practice, see the Special 50th Anniversary issue of *Theory Into Practice* (Gaskill, 2013).

MyLab Education **Self-Check 1.3**

Design-based research

Practitioners identify research questions based on problems of practice, then researchers gather and analyze the data to address those problems.

Action research

Systematic observations or tests of methods conducted by teachers or schools to improve teaching and learning for their students.

MyLab Education Video Example 1.3

A Spanish teacher conducts research in her classroom and explains the results and the impact on her students. Notice the types of changes her students reported after the teacher implemented formative assessments.

Theories for Teaching

As we saw earlier, the major goal of educational psychology is to understand what happens when someone teaches something to someone else in some setting (Berliner, 2006; Schwab, 1973). Reaching this goal is a slow process. There are very few landmark studies that answer a question once and for all. There are so many different kinds of students, teachers, tasks, and settings; and besides, human beings are pretty complicated. To deal with this complexity, research in educational psychology examines limited aspects of a situation—perhaps a few variables at a time or life in one or two classrooms. If enough studies are completed in a certain area and findings repeatedly point to the same conclusions, we eventually arrive at a **principle**. This is the term for an established relationship between two or more factors—between a certain teaching strategy, for example, and student achievement.

Another tool for building a better understanding of the teaching and learning processes is *theory*. The commonsense notion of theory (as in “Oh well, it was only a theory”) is “a guess or hunch.” But the scientific meaning of *theory* is quite different. “A **theory** in science is an interrelated set of concepts that is used to explain a body of data and to make predictions about the results of future experiments” (Stanovich, 1992, p. 21). Educational psychologists have developed explanations for the relationships among many variables and even whole systems of relationships. There are theories to explain how language develops, why goals affect motivation, and, as noted earlier, how people learn.

You will encounter many theories of development, learning, and motivation in this book. Theories are the beginning and ending points of the research cycle. In the beginning, theories provide the research **hypotheses** to be tested (predictions about what will happen) or the questions examined. For example, Piaget’s theory might suggest the hypothesis that instruction cannot teach young children to think more abstractly, whereas Vygotsky’s theory might suggest the competing hypothesis that instruction will be effective. Of course, at times, psychologists don’t know enough to state hypotheses, so they just ask *research questions*. An example question might be: “Is there a difference in the Internet usage of male and female adolescents from different ethnic groups?”

Research is a continuing cycle that involves:

- Clear specification of hypotheses, problems, or questions based on current theories
- Systematic gathering and analysis of all kinds of information (data) about the questions from well-chosen research participants in carefully selected situations
- Interpretation and analysis of the data gathered using appropriate methods to answer the questions.
- Modification and improvement of explanatory theories based on the results of those analyses.
- Formulation of new and better hypotheses based on the improved theories . . . and on and on.

This empirical process of collecting data to test and improve theories is repeated over and over. **Empirical** means “based on data.” When researchers say that identifying an effective antibiotic or choosing a successful way to teach reading is an “empirical question,” they mean that you need data and evidence to make the call. Constructing decisions from empirical analyses protects psychologists from developing theories based on personal biases, rumors, fears, faulty information, or preferences (Mertler & Charles, 2005). Good research is self-correcting. If predictions do not play out or if answers to carefully formulated questions do not support current best understandings (theories), then the theories have to be changed. You can use the same kind of systematic and self-correcting thinking in your work with students.

Few theories explain and predict perfectly. In this book, you will see many examples of educational psychologists taking different theoretical positions and disagreeing on the overall explanations of such broad topics as learning and motivation. Because no one theory offers all the answers, it makes sense to consider what each has to offer.

So why, you may ask, is it necessary to deal with theories? Why not just stick to principles? The answer is that both are useful. Principles of classroom management,

Principle Established relationship between factors.

Theory Integrated statement of principles that attempts to explain a phenomenon and make predictions.

Hypothesis/hypotheses A prediction of what will happen in a research study based on theory and previous research.

Empirical Based on systematically collected data.

for example, will give you help with specific problems. A good theory of classroom management, on the other hand, will give you a new way of thinking about discipline problems; it will give you cognitive tools for creating solutions to many different problems and for predicting what might work in new situations. A major goal of this book is to provide you with the best and the most useful theories of development, learning, motivation, and teaching—those that have solid evidence behind them. Although you may prefer some theories to others, consider them all as ways of understanding the challenges teachers face.

I began this chapter by asserting that Educational Psychology is my favorite topic, as well as a key source of knowledge and skills for teaching. I end this chapter with one more bit of evidence for my enthusiasm. Educational psychology will help you support student learning—the goal of all teaching.

Supporting Student Learning

In an article in the *Educational Psychologist*, a major journal in our field, Jihyun Lee and Valerie Shute (2010) reported sifting through thousands of studies of student learning conducted over the course of 60 years, seeking to identify those that had direct measures of student achievement in reading and mathematics. Then they narrowed their focus to studies with strong effects. About 150 studies met all their rigorous criteria. Using the results from these studies, Lee and Shute identified about a dozen variables that were directly linked to K–12 student achievement. The researchers grouped these factors into two categories: *student personal factors* and *school and social-contextual factors*, as you can see in Table 1.4. When I read this article, I was pleased to see that my favorite subject, educational psychology, provides a base for developing knowledge and skills in virtually every area except principal leadership (for that subject you have to consult a book I wrote with my husband on principals as instructional leaders—Woolfolk Hoy & Hoy, 2013).

As you can see in Table 1.4, this text should help you become a capable and confident teacher who can get students engaged in the classroom learning community—a community that respects its members. This book will guide you toward becoming a teacher who helps students develop into interested, motivated, self-regulated, and confident learners. As a consequence, you will be able to set high expectations for your students, rally the support of parents, and build your own sense of efficacy as a teacher.

TABLE 1.4 • Research-Based Personal and Social-Contextual Factors That Support Student Achievement in K–12 Classrooms (Continued)

STUDENT PERSONAL FACTORS	EXAMPLES	WHERE IN THIS TEXT
Learning Strategies		
Cognitive Strategies	Directly teach knowledge and skills that support student learning and deep processing of valuable information (e.g., summarizing, inferring, applying, and reasoning).	Chapters 7–9, 14
Metacognitive Strategies	Directly teach students to monitor, regulate, and evaluate their own cognitive processes, strengths, and weaknesses as learners; teach them about when, where, why, and how to use specific strategies.	Chapters 7–9, 11
Behavioral Strategies	Directly teach students strategies and tactics for managing, monitoring, and evaluating their action, motivation, affect, and environment, such as skills in: time management test taking help seeking note taking homework management	Chapters 7–14
SOCIAL-CONTEXTUAL FACTORS	EXAMPLES	WHERE IN THIS TEXT
School Climate		
Academic Emphasis	Set high expectations for your students, and encourage the whole school to do the same; emphasize positive relations with the school community.	Chapters 11–13
Teacher Variables	If possible, teach in a school with the positive qualities of collective efficacy, teacher empowerment, and sense of affiliation.	Chapters 1, 11, 13
Principal Leadership	If possible, teach in a school with the positive qualities of collegiality, high morale, and clearly conveyed goals.	See Woolfolk Hoy and Hoy (2013).
Social-Familial Influences		
Parental Involvement	Support parents in supporting their children's learning.	Chapters 3–6, 12
Peer Influences	Create class and school norms that honor achievement, encourage peer support, and discourage peer conflict.	Chapters 3, 10, 13, 15

▼ SUMMARY

Learning and Teaching Today (pp. 32–36)

What are classrooms like today? About 25% of U.S. children under 18 are living in immigrant families. It is likely that by 2060, nearly 20% of the U.S. population will be foreign born, and people of Hispanic origin will comprise almost 30% of that population. By 2044, there will be no majority race or ethnic group in the United States; every American will be a member of a minority group. Around 22% of American children currently live in poverty. Over half of school-age students with disabilities receive most of their education in general education classrooms. Even though students in classrooms are increasingly diverse in race, ethnicity, language, and economic level, teachers are much less diverse—the percentage of White teachers is increasing, while the percentage of Black teachers is falling. This book is about understanding the complex processes of development, learning, motivation, teaching, and assessment so that you can become a capable and confident teacher with a high but authentic sense of efficacy.

What are NCLB and ESSA? The No Child Left Behind Act (NCLB) of 2002 required extensive standardized achievement testing in reading and mathematics in grades 3 through 8 (and once more in high school) and in science once in each grade span: elementary, middle, and high school. The law also required that all students in the schools reach full proficiency in these subjects by the end of the 2013–2014 school year; it didn't happen. Largely because there were major penalties for schools that did not make adequate yearly progress (AYP) toward full proficiency, a number of negative consequences followed in the wake of the tests—cheating, teaching to the test, narrowing the curriculum to a few subjects, driving teachers out of the classroom. In 2015, President Barack Obama signed the Every Student Succeeds Act (ESSA) that replaced NCLB and returned most of the control to the states. There is still testing in the same grades and subjects, but states and local schools decide when and how to test and how to intervene in the lowest performing schools. ESSA also supports more access to early childhood education and the establishment of teacher education academies outside colleges and universities.

What evidence is there that teachers make a difference? Several studies speak to the power of teachers in the lives of students. The first found that the quality of the teacher–student relationship in kindergarten predicted several aspects of school success through the eighth grade. The second study found similar results for students from preschool through fifth grade, a finding confirmed by almost 100 students in countries around the world. The third study examined math achievement for students in two large school districts as they moved through third, fourth, and fifth grades. Again, the quality of the teacher made a difference: Students who had three high-quality teachers in a row were way ahead of peers who spent 1 or more years with less-competent teachers. In a study that followed children from third through fifth grade, two factors helped children with lower skills in mathematics

begin to close the achievement gap: higher-level (not just basic skills) instruction and positive relationships with teachers. Similar findings hold for beginning teachers.

What Is Good Teaching? (pp. 37–41)

Good teachers are committed to their students. They must deal with a wide range of student abilities and challenges: different languages, different home situations, and different abilities and disabilities. They must adapt instruction and assessment to students' needs. The whole time these experts are navigating through the academic material, they also are taking care of the emotional needs of their students, propping up sagging self-esteem, and encouraging responsibility. From the first day of class, they carefully plan and teach the basic procedures for living and learning in their classes.

What are some research-based models of effective teaching?

Charlotte Danielson describes a *Framework for Teaching*, which has 22 components organized into four domains or areas of teaching responsibility: Planning and Preparation, Classroom Environment, Instruction, and Professional Responsibilities. This framework is the basis for a widely used system of teacher evaluation. TeachingWorks, a national project based at the University of Michigan and dedicated to improving teaching practice, has identified 19 high-leverage teaching practices, defined as actions that are central to teaching and useful across most grade levels, academic subjects, and teaching situations. Finally, the Bill and Melinda Gates Foundation launched the Measures of Teaching Effectiveness (MET) Project, a research partnership between 3,000 teachers and research teams at dozens of institutions, that has identified a three-part system for evaluating good teaching that includes gains on state achievement tests (weighted at about 33% to 50%), student perceptions of teachers, and classroom observations using the Danielson Framework for Teaching. The latter two make up the 66% to 50% of the weighting in the evaluations.

What are the concerns of beginning teachers? Learning to teach is a gradual process. The concerns and problems of teachers change as they grow in their ability. During the beginning years, attention tends to be focused on maintaining discipline, motivating students, accommodating differences among students, evaluating students' work, dealing with parents, and getting along with other teachers. Even with these concerns, many beginning teachers bring creativity and energy to their teaching and improve every year. The more experienced teacher can move on to concerns about professional growth and effectiveness in teaching a wide range of students.

The Role of Educational Psychology (pp. 42–52)

What is educational psychology? Educational psychology has been linked to teaching since it began in the United States over a century ago. The goals of educational psychology are

to understand and to improve the teaching and learning processes. Educational psychologists develop knowledge and methods; they also use the knowledge and methods of psychology and other related disciplines to study learning and teaching in everyday situations. Educational psychologists examine what happens when someone/something (a teacher or parent or computer) teaches something (math or weaving or dancing) to someone else (student or co-worker or team) in some setting (classroom or theater or gym).

What are the research methods in educational psychology?

Correlational methods identify relationships and allow predictions. A correlation is a number that indicates both the strength and the direction of a relationship between two events or measurements. The closer the correlation is to either +1.00 or -1.00, the stronger the relationship. Experimental studies allow researchers to detect causes, not just make predictions. Experimental studies should help teachers implement useful changes. Instead of just observing and describing an existing situation, the investigators introduce changes and note the results. Quasi-experimental studies meet most of the criteria for true experiments, with the important exception being that the participants are not assigned to groups at random. Instead, existing groups such as classes or schools participate in the experiments. In ABAB experimental designs, researchers examine the effects of treatments on one or more people, often by using a baseline/intervention/-baseline/-intervention approach. Clinical interviews, case studies, and ethnographies look in detail at the experiences of a few individuals or groups. If participants are studied over time, the research is called *longitudinal*. If researchers intensively study cognitive processes in the midst of change—as the change is actually happening—over several sessions or weeks, then the research is *microgenetic*. No matter what method is used, results from the research are used to further develop and improve theories, so that even better hypotheses and questions can be developed to guide future research.

What is the difference between qualitative and quantitative research?

There is a general distinction between qualitative and quantitative research. These are large categories and, like many categories, a bit fuzzy at the edges. Qualitative methods such as case studies and ethnographies use words, dialogue, events, themes, and images as data. The goal is to explore specific situations or people in depth and to understand the meaning of the events to the people involved in order to tell their story. Quantitative research uses numbers, measurement, and statistics to assess levels or sizes of relationships among variables or differences between groups—correlational and experimental

research are examples. Different types of research can answer different questions. Today many researchers are using *mixed methods* to study questions both broadly and deeply. There are three basic ways of combining methods. First, a researcher collects both quantitative and qualitative data at the same time, then merges and integrates the data in the analyses. Second, the researcher collects quantitative data first, for example, from surveys or observation instruments, and then follows this by performing in-depth qualitative interviews of selected participants. Often the goal here is to explain or look for causes. Finally, the sequence can be reversed—the researcher first conducts interviews or case studies to identify research questions, then collects quantitative data as guided by the qualitative findings. Here the goal may be to explore a situation deeply.

Scientifically-based research, which is more consistent with quantitative research, systematically uses observations or experiments to gather valid and reliable data; involves rigorous and appropriate procedures for gathering and analyzing the data; is clearly described so it can be repeated by others; and has been rigorously reviewed by appropriate, independent experts. Evidence-based practices, the kind that must be used to intervene in failing schools under the ESSA law, are grounded in results of systematic, rigorous research. When teachers or schools make systematic observations or test out methods to improve teaching and learning for their students, they are conducting action research.

Distinguish between principles and theories. A principle is an established relationship between two or more factors—between a certain teaching strategy, for example, and student achievement. A theory is an interrelated set of concepts that is used to explain a body of data and to make predictions. The principles from research offer a number of possible answers to specific problems, and the theories offer perspectives for analyzing almost any situation that may arise. Research is a continuing cycle that involves clear specification of hypotheses or questions based on good theory, systematic gathering and analyzing of data, interpretation and analysis of the data gathered using appropriate methods to answer the questions, modification and improvement of explanatory theories based on the results, and the formulation of new, better questions based on the improved theories.

What key factors support student learning? A synthesis of about 150 studies of student learning found two broad categories of influence: *student personal factors* and *school and social-contextual factors*. When I read this article, I was pleased to see that my favorite subject, educational psychology, provides a base for developing knowledge and skills in virtually every area except principal leadership.

MULTIPLE-CHOICE QUESTIONS

- Which of the following does NOT characterize today's classrooms and teaching around the world?
 - Classrooms and schools in many countries today are comprised of students from diverse backgrounds.
 - Compared to decades ago, most students today have access to advanced technological devices (e.g., computer, TVs, tablets).
 - Most students today are expected to master more than one language and skillset.
 - Increasing access to social media has exposed students to information and diversity, which makes diversity and inclusion less challenging than ever.
- Self-efficacy is an important part of effective teaching. Which of the following statements is FALSE regarding self-efficacy in teachers?
 - Teachers' self-efficacy refers to a teacher's belief that they would be able to handle and help even the most difficult students in a classroom.
 - Teachers with a high sense of efficacy persevere longer in their teaching endeavors, which may later produce better student achievements.
 - In most cases, a teacher's self-efficacy starts low when they begin their career and progressively becomes stronger.
 - Teachers with a high sense of efficacy are more satisfied with their jobs and experience lower rates of burnout.
- Often, many of us make some assumptions regarding teaching processes based on common sense or intuitions that are inconsistent with findings from actual research on the subject. Given below are some suggestions for teachers on handling situations encountered in the classroom. Which of the following suggestions is TRUE?
 - Teachers should actively reach out to lower-achieving students because they might not be aware of their low performance and/or be too embarrassed to seek help.
 - We should never encourage exceptionally intelligent students to skip grades because they are not physically, emotionally, and socially ready to deal with older classmates.

- Teachers should always give students more control over their own learning; for example, they could let students select learning materials that they find engaging.
- Teachers should avoid providing unsought assistance as it leads students to believe that they do not have the ability to succeed.

CONSTRUCTED-RESPONSE QUESTIONS

Case

Jenny was interested in introducing electronic clickers—a device that captures students' responses electronically and helps teachers track and evaluate students' performance on the spot—to classrooms as she entered the field as a first-year high school teacher. Her belief in the usefulness of clickers for high school students was inspired by her own experience during her tertiary education as well as by her more recent understanding of the benefits of electronic clickers (e.g., clickers were found to produce higher performance outcomes in classes, encourage attendance, enhance students' learning experience, aid in identifying important core course concepts, and make the interaction between teacher and students more lively, etc.). She discussed her idea with the school principal. Considering the cost of electronic clickers on the school and the parents, the principal recommended that Jenny first gather some evidence for the positive effects of electronic clickers on her own students' learning outcomes, before they deliberated over generalizing its benefits to the entire school.

- Identify Jenny's goals and explain briefly whether you agree or disagree that electronic clickers should be introduced in her classroom.
- If Jenny were to design a study to gather some preliminary evidence for the effect of clickers on her students' performance, which research method would you recommend, and why?

▼ WHAT WOULD THEY DO?

TEACHERS' CASEBOOK: Leaving No Student Behind

Here is how several expert teachers said they would prepare a highly diverse group of students for spring achievement tests and readiness for college and career.

JENNIFER PINCOSKI • Learning Resource Teacher: K–12
Lee County School District, Fort Myers, FL

One of the advantages for teachers in this situation is that many of the strategies that are effective for students with learning disabilities are also effective for second-language learners. Even students who are meeting benchmarks will benefit from these supports. Some of these strategies include labeling items throughout the classroom for language/vocabulary acquisition, providing visual supports whenever possible, and using a variety of graphic organizers. Cooperative learning groups and the total physical response (TPR) method can also help in the development of both language skills and content knowledge. Activities can be tiered to match students' levels of understanding, and, to demonstrate their learning, students can be offered multiple assignment options from which to choose.

Exposing students to new vocabulary and content through auditory, visual, AND hands-on instruction will yield the best results. Broken down to its most basic level, this philosophy can be summarized by the proverb, "Tell me and I'll forget; show me and I'll remember; involve me and I'll understand." Students should be active participants in the learning process, not spectators.

JESSICA N. MAHTABAN • Eighth-Grade Math Teacher
Woodrow Wilson Middle School, Clifton, NJ

The first thing to address is survival. Each student must learn his/her name, address, and phone number. It is crucial for all students to know this information in case of any type of emergency. Afterward, the students will become familiar with the classroom routines and expectations. Once the students are comfortable with the routines and expectations, they will be able to focus on language. The intern, administration, parents, and I must meet frequently to work cooperatively on making projects and goals for each student.

During any lesson I would provide visual cues (gestures, pictures, objects) with verbal instruction. I would speak to the students in short sentences and give clear examples of what is expected from them. The intern and I will interact with students as they work independently or cooperatively during an activity. We will also check comprehension frequently, so that we can help any student that does not understand.

PAUL DRAGIN • ESL Teacher, Grades 9–12
Columbus East High School, Columbus, OH

Multiple obstacles are posed in this situation. The scenario presents two pieces of information that I would key in on. One is that problems in reading seem to be the most common. This is the challenge I would place as the number one priority due to its preeminence in terms of predicting future academic success. Scoring well on the achievement tests and doing well in college are not realistic expectations without reading success. The other piece of information that is advantageous is the student intern from the local college. With reading as the focus, I would instruct the intern on some basic reading diagnostics to get a clearer picture of each student's reading level. From there, we could choose texts that would be appropriate to increase comprehension and fluency. With two instructors in the room, we would be better equipped for small-group instruction to target the various reading levels. This targeted reading instruction would be a benefit to the intern as well as the students, because the intern's services would be vital to instruction and together we would assist the students in their reading comprehension and subsequent language acquisition.

PAULA COLEMERE • Special Education Teacher–English, History
McClintock High School, Tempe, AZ

Before even beginning to teach this group of students, I would set my room up for success. Students can be distracted by too many things on the walls; therefore, everything I choose to display would be very deliberate. To do this, I would start with a blank slate and take everything off of the walls. I would label objects, such as the door, pencil sharpener, desks, and so on, with signs to help the students who are English language learners (ELLs) to build vocabulary. I would save an area to create a "word wall" for content area vocabulary; this will aid both the students who are ELLs and the students with special needs. It would be important to me to educate myself on the background of my students and where they come from. This would help me to make a personal connection with each student and it would help me to understand cultural differences when making contact with the family. It is also important to have an understanding of what is happening in their home countries to try to make connections to learning based on their experiences. Finally, graphic organizers would be a key part of my lesson planning because they help students to organize information.

chapter two

COGNITIVE DEVELOPMENT

WHAT WOULD YOU DO?

TEACHERS' CASEBOOK: Symbols and Cymbals

The district curriculum guide calls for a unit on poetry, including lessons on *symbolism* in poems. You are concerned that many of your fourth-grade students may not be ready to understand this abstract concept. To test the waters, you ask a few students what a *symbol* is.

"It's sorta like a big metal thing that you bang together." Tracy waves her hands like a drum major.

"Yeah," Sean adds, "My sister plays one in the high school band."

You realize they are on the wrong track here, so you try again. "I was thinking of a different kind of symbol, like a ring as a symbol of marriage or a heart as a symbol of love, or. . . ."

You are met with blank stares.

Trevor ventures, "You mean like the Olympic torch?"

"And what does that symbolize, Trevor?" you ask.

"Like I said, a torch." Trevor wonders how you could be so dense.

CRITICAL THINKING

- What do these students' reactions tell you about children's thinking?
- How would you approach this unit?
- What more would you do to "listen" to your students' thinking so you could match your teaching to their level of thinking?
- How would you give your students concrete experiences with symbolism?
- How will you decide if the students are not developmentally ready for this material?

Agsandrew/Shutterstock

OVERVIEW AND OBJECTIVES

What is going on with Trevor? In this chapter, you will find out. We begin with a definition of *development* and examine three basic questions. Psychologists have debated the answers to these questions for many years: nature versus nurture, continuity versus discontinuity, and critical versus sensitive periods for development. Next we look at general principles of human development that most psychologists affirm. To understand cognitive development, we begin by studying how the brain works and then explore the ideas of two of the most influential cognitive developmental theorists, Jean Piaget and Lev Vygotsky. Piaget's ideas have implications for teachers about how their students think and what they can learn. We will consider criticisms of his ideas as well. The work of Lev Vygotsky, a Russian psychologist, highlights the important role teachers and parents play in the cognitive development of the child. Vygotsky's theory is becoming more and more influential in the field of child development. By the time you have completed this chapter, you should be able to:

- Objective 2.1 Provide a definition of development that takes into account three agreed-upon principles and describe three continuing debates about development, along with current consensus on these questions.
- Objective 2.2 Summarize research on the physical development of the brain and possible implications for teaching.
- Objective 2.3 Explain the principles and stages presented in Piaget's theory of cognitive development, including criticisms of his theory.
- Objective 2.4 Explain the principles presented in Vygotsky's theory of development, including criticisms of his theory.
- Objective 2.5 Discuss implications of Piaget's and Vygotsky's theories for teaching.

Summary and Key Terms

Teachers' Casebook—Symbols and Cymbals: What Would They Do?

Development Orderly, adaptive changes we go through between conception and death; these developmental changes remain for a reasonably long period of time.

A DEFINITION OF DEVELOPMENT

In the next few chapters, as we explore how children develop, we will encounter some surprising situations.

- Leah, a 5-year-old, is certain that rolling out a ball of clay into a snake creates more clay.
- A 9-year-old child in Geneva, Switzerland, firmly insists that it is impossible to be Swiss and Genevan at the same time: "I'm already Swiss. I can't also be Genevan."
- Jamal, a very bright elementary school student, cannot answer the question, "How would life be different if people did not sleep?" because he insists, "People HAVE TO SLEEP!"
- A 2-year-old brings his own mother to comfort a friend who is crying, even though the friend's mother is available, too.

What explains these interesting events? You will soon find out, because you are entering the world of child and adolescent development.

The term **development** in its most general psychological sense refers to certain changes that occur in human beings (or animals) between conception and death. The term is not applied to all changes, but rather to those that appear in orderly ways and remain for a reasonably long period of time. A temporary change caused by a brief illness, for example, is not considered a part of development. Human development can be divided into a number of different aspects. **Physical development**, as you might guess, deals with changes in the body. **Personal development** is the term generally used for changes in an individual's identity and personality. **Social development** refers to changes in the way an individual relates to others. And **cognitive development** refers to changes in thinking, reasoning, and decision making.

Many changes during development are simply matters of growth and maturation. **Maturation** refers to changes that occur naturally and spontaneously and that are, to a large extent, genetically programmed. Such changes emerge over time and are relatively unaffected by environment, except in cases of malnutrition or severe illness. Much of a person's physical development falls into this category. Other changes are brought about through learning, as individuals interact with their environment. Such changes make up a large part of a person's social development. But what about the development of thinking and personality? Most psychologists agree that in these areas, both maturation and interaction with the environment (or *nature* and *nurture*, as they are

sometimes called) are important, but they disagree about the amount of emphasis to place on each one. Nature versus nurture is one of three continuing discussions in theories of development.

Three Questions Across the Theories

Because there are many different approaches to research and theory, there are some continuing debates about key questions surrounding development.

WHAT IS THE SOURCE OF DEVELOPMENT? NATURE VERSUS NURTURE. Which is more important in development, the “nature” of an individual (heredity, genes, biological processes, maturation, etc.) or the “nurture” of environmental contexts (education, parenting, culture, social policies, etc.)? This debate has raged for at least 2,000 years and has accumulated many labels along the way, including “heredity versus environment,” “biology versus culture,” “maturation versus learning,” and “innate versus acquired abilities.” In earlier centuries, philosophers, poets, religious leaders, and politicians argued the question. Even in scientific explanations, the pendulum has swung back and forth between nature and nurture (Cairns & Cairns, 2006; Overton, 2006).

Scientists now bring new tools to the discussion as they can map genes or trace the effects of drugs on brain activity, for example (Gottlieb, Wahlsten, & Lickliter, 2006). Today the environment is seen as critical to development, but so are biological factors and individual differences. In fact, some psychologists assert that behaviors are determined 100% by biology and 100% by environment—they can’t be separated (P. H. Miller, 2011). Current views emphasize complex **coactions** (joint actions) of nature and nurture. For example, a child born with a very easygoing, calm disposition will likely elicit different reactions from parents, playmates, and teachers than a child who is often upset and difficult to soothe; this shows that individuals are active in constructing their own environments. But environments shape individuals as well—if not, what good would education be? So today, the *either/or* debates about nature and nurture are of less interest to educational and developmental psychologists. As a pioneering developmental psychologist said over 100 years ago, the more exciting questions involve understanding how “both causes work together” (Baldwin, 1895, p. 77).

WHAT IS THE SHAPE OF DEVELOPMENT? CONTINUITY VERSUS DISCONTINUITY. Is human development a continuous process of increasing abilities, or are there leaps to new stages when abilities actually change? A continuous process would be like gradual improvement in your running endurance through systematic exercise. A discontinuous change (also called *qualitative*) would be like many of the changes in humans during puberty, such as the ability to reproduce—an entirely different ability.

You can think of continuous or quantitative change like walking up a ramp to go higher and higher: Progress is steady. A discontinuous or qualitative change is more like walking up stairs: There are level periods, and then you ascend the next step all at once. Piaget’s theory of cognitive development, described in the next section, is an example of *qualitative*, discontinuous change in children’s thinking abilities. But other explanations of cognitive development based on learning theories emphasize gradual, continuous, *quantitative* change.

TIMING: IS IT TOO LATE? CRITICAL VERSUS SENSITIVE PERIODS. Are there critical periods during which certain abilities, such as language, need to develop? If those opportunities are missed, can the child still “catch up”? These are questions about timing and development. Many earlier psychologists, particularly those influenced by Freud, believed that early childhood experiences were critical, especially for emotional/social and cognitive development. But does early toilet training really set all of us on a particular life path? Probably not. More recent research shows that later experiences are powerful, too, and can change the direction of development. Most psychologists today talk about **sensitive periods**—not critical periods. There are “windows of opportunity”—times when a person is especially ready for or responsive to certain experiences (Scalise & Felds, 2017).

BEWARE OF EITHER/OR. As you might imagine, these debates about development proved too complicated to be settled by splitting alternatives into either/or possibilities (Griffins & Gray, 2005). Today, most psychologists view human development, learning, and motivation as a set of interacting and coacting contexts, from the inner biological structures and processes that influence development such as genes, cells, nutrition, and disease, to the external factors of families, neighborhoods, social relationships, educational and health institutions, public policies, time periods, historical events, and so on.

Physical development

Changes in body structure and function over time.

Personal development

Changes in personality that take place as one grows.

Social development

Changes over time in the ways we relate to others.

Cognitive development

Gradual orderly changes by which mental processes become more complex and sophisticated.

Maturation Genetically programmed, naturally occurring changes over time.

Coactions Joint actions of individual biology and the environment—each shapes and influences the other.

Sensitive periods Times when a person is especially ready to learn certain things or responsive to certain experiences.

So the effects of a childhood disease on the cognitive development of a child born in the sixteenth century to a poor family and treated by bloodletting or leeches will be quite different than the effect of the same disease on a child born in 2018 to a wealthy family and given the best treatment available for that time period. Throughout the rest of this book, we will try to make sense of development, learning, motivation, and teaching without falling into the *either/or trap*.

General Principles of Development

Although there is disagreement about exactly how development takes place, there are a few general principles almost all theorists would support.

1. *People develop at different rates.* In your own classroom, you will have a broad range of examples of different developmental rates. Some students will be larger, better coordinated, or more mature in their thinking and social relationships. Others will be much slower to mature in these areas. Except in rare cases of very rapid or very slow development, such differences are normal and should be expected in any large group of students.
2. *Development is relatively orderly.* People develop abilities in a logical order. In infancy, they sit before they walk, babble before they talk, and see the world through their own eyes before they can begin to imagine how others see it. In school, they will master addition before algebra, Harry Potter before Shakespeare, and so on. But “orderly” does not necessarily mean linear or predictable—people might advance, stay the same for a period of time, or even go backward.
3. *Development takes place gradually.* Very rarely do changes appear overnight. A student who cannot manipulate a pencil or answer a hypothetical question may well develop this ability, but the change is likely to take time.

Computerized axial tomography (CAT) A technique that uses X-ray technology to provide enhanced, 3-dimensional images of the part of the body scanned.

Positron emission tomography (PET) A method of localizing and measuring brain activity using computer-assisted motion pictures of the brain.

Electroencephalograph (EEG) A technique that measures electrical patterns in the brain created by neuron movements using electrodes attached to the scalp.

Event-related potential (ERP) Measurements that assess electrical activity of the brain through the skull or scalp.

Functional magnetic resonance imaging (fMRI) An MRI is an imaging technique that uses a magnetic field along with radio waves and a computer to create detailed pictures of the inside of the body. A functional MRI uses the MRI to measure the tiny changes that take place in the brain during brain activity.

MyLab Education [Self-Check 2.1](#)

THE BRAIN AND COGNITIVE DEVELOPMENT

If you have taken an introductory psychology class, you have read about the brain and nervous system. You probably remember that there are several different areas of the brain and that certain areas are involved in particular processes. For example, the *brain stem* handles basic functions such as heart rate, breathing, and blood pressure as well as levels of arousal such as sleeping and wakeful attention. The feathery looking *cerebellum* coordinates and orchestrates balance and smooth, skilled movements—from the graceful gestures of the dancer to the everyday action of eating without stabbing yourself in the nose with a fork. The cerebellum may also play a role in higher cognitive functions such as learning. The *hippocampus* is critical in recalling new information and recent experiences, while the *amygdala* directs emotions and aggression. The *thalamus* is involved in our ability to learn new information, particularly if it is verbal. The *corpus callosum* connects the two hemispheres of the brain to allow communication between them for complex mental processing. The *frontal lobe* is the area that sets humans apart by enabling us to process information for planning, remembering, making decisions, solving problems, and thinking creatively (Schunk, 2016). Figure 2.1 shows the various regions of the brain.

Advances in brain imaging techniques have allowed scientists remarkable access to the functioning brain. For example, **computerized axial tomography (CAT)** scans give three-dimensional images of the brain. **Positron emission tomography (PET)** scans can track brain activity under different conditions. An **electroencephalograph (EEG)** measures electrical patterns in the brain, and **event-related potential (ERP)** uses EEG data to study the brain as people perform activities such as reading or learning vocabulary words. **Functional magnetic resonance imaging (fMRI)** shows how blood flows within the brain when children or adults do different cognitive tasks. Finally, a new approach,

FIGURE 2.1

REGIONS OF THE BRAIN

near-infrared optical tomography (NIR-OT) uses infrared light through the scalp to assess brain activity. Table 2.1 on the next page summarizes what each of the techniques can and cannot do.

Let's begin our look at the brain by examining its tiny components: neurons, synapses, and glial cells.

The Developing Brain: Neurons

A newborn baby's brain weighs about 1 pound, barely one-third of the weight of an adult brain. But this infant brain has billions of **neurons**, the specialized nerve cells that accumulate and transmit information (in the form of electrical activity) in the brain and other parts of the nervous system. Neurons are a grayish color, so they sometimes are called the *gray matter* of the brain. One neuron has the information processing capacity of a small computer. That means the processing power of one 3-pound human brain is likely greater than all the computers in the world. Of course, computers do many things, like calculate square roots of large numbers, much faster than humans can (J. R. Anderson, 2015). These incredibly important neuron cells are tiny; about 30,000 could fit on the head of a pin (Sprenger, 2010). Scientists once believed that all the neurons a person would ever possess were present at birth, but now we know that the production of new neurons, **neurogenesis**, continues into adulthood, especially in the hippocampus region (Koehl & Abrous, 2011; Scalise & Felde, 2017).

Neuron cells send out long arm- and branch-like fibers called axons and dendrites to connect with other neuron cells. The fiber ends from different neurons don't actually touch; there are tiny spaces between them, about one billionth of a meter in length, called **synapses**. Neurons share information by using electrical signals and by releasing chemicals that jump across the synapses. *Axons* transmit information out to muscles, glands, or other neurons; *dendrites* receive information and transmit it to the neuron cells themselves. Connections between neurons by these synaptic transmissions become stronger with use or practice and weaker when not used. The neural pathways reinforced by use form memory traces that are the end result of learning (Scalise & Felde, 2017; Schunk, 2016). So the strength of these synaptic connections is dynamic—always changing as learning occurs. This is called **synaptic plasticity**, or just **plasticity**, a very important concept for educators, as you will see soon. Researchers have found that physical exercise plays a critical role in maintaining a healthy, plastic brain (Doidge, 2015; Dubinsky, Roehrig, & Varma, 2013). Figure 2.2 on page 65 shows these components of the neuron system (J. R. Anderson, 2015).

At birth, each of the child's approximately 100 to 200 billion neurons has about 2,500 synapses. However, the fibers that reach out from the neurons and the synapses

Near-infrared optical tomography (NIR-OT) A technique that uses an optical fiber to transmit near-infrared light through the scalp and into the brain. Some of the light is reflected back, indicating blood flow and oxygenation in the blood that reveal brain activity.

Neurons Nerve cells that store and transfer information.

Neurogenesis The production of new neurons.

Synapses The tiny space between neurons—chemical messages are sent across these gaps.

Synaptic plasticity The brain's tendency to remain somewhat adaptable or flexible.

Plasticity The brain's tendency to remain somewhat adaptable or flexible.

TABLE 2.1 • Brain Imaging Techniques

Advances in brain imaging have led to greater understanding of how the brain functions. Each technique can give some kinds of information, but not others.

COMMON NAME	WHAT IT DOES	EXAMPLE USES	LIMITATIONS/ WHAT IT CAN'T DO
CAT Scan Computerized Axial Tomography	Uses X-ray technology to provide enhanced, 3-dimensional images of the brain.	Locating and studying tumors or lesions in the brain.	Cannot use too often because of radiation exposure; does not give detailed information about brain activity.
PET Scan Positron Emission Tomography	Shows the extent of activity in different parts of the brain. A small amount of radioactive glucose is injected into the body and carried to the brain. Greater brain activity in various areas uses more glucose and shows up as brighter colors on computerized brain maps.	Studying how the brain works and which areas are more or less involved in different cognitive activities such as reading; diagnosing brain disease such as tumors, strokes, and dementia.	Because radioactive injections are needed, cannot do many sessions; because there is a brief lag, does not capture fast-paced neural activity; tells more about <i>where</i> in general the activity takes place than <i>when</i> it does.
EEG Electroencephalograph	Measures electrical patterns in the brain created by neuron movements using electrodes attached to the scalp. No drugs or radiation are required.	Studying sleep disorders, epilepsy, language disorders, and cognitive load (Chapter 8).	Does not provide either 2- or 3-dimensional pictures of the brain; reflects activity for the whole brain and cannot show specifically where activity is occurring.
ERP Event-Related Potentials	Provides a calculation based on EEG data that reflects the brain's response to a stimulus or event.	Studying sensory and cognitive activity, especially language, as well as visual problems and brain disorders.	Is good at assessing speed of neural activity but not at identifying location.
fMRI Functional Magnetic Resonance Imaging	Shows moment-by-moment blood flow within the brain associated with neural activity when children or adults do different cognitive tasks, revealing the amount of work done in certain areas. No radiation or injections are necessary.	Studying brain processes and structures related to perception, emotion, thinking, and action; diagnosing when to use chemicals to treat strokes; mapping patients' brains before surgery.	Has few limitations and has largely replaced PET scans, but there is a brief lag between changes in brain activity and the changes in blood flow picked up by the fMRI.
NIR-OT Near-infrared Optical Tomography	Uses an optical fiber to transmit near-infrared light through the scalp and into the brain. Some of the light is reflected back, indicating blood flow and oxygenation in the blood that reveal brain activity.	Studying brain processes and changes during particular activities, social interactions, classroom learning. Not invasive, no chemicals or radiation are used; can be mobile and used over longer periods of time.	Has few limitations except it can only detect activity a few centimeters into the brain where the light can penetrate.

between the fiber ends increase during the first years of life, perhaps into adolescence or longer. By ages 2 to 3, each neuron has around 15,000 synapses; children this age have many more synapses than they will have as adults. In fact, they are *oversupplied* with the neurons and synapses they will need to adapt to their environments. However, only those neurons that are used will survive, and unused neurons will be “pruned.” This pruning is

FIGURE 2.2

A SINGLE NEURON

Each neuron (nerve cell) includes dendrites that bring in messages and an axon that sends out messages. This is a single neuron, but each neuron is in a network with many others.

necessary and supports cognitive development. Researchers have found that some developmental disabilities are associated with a gene defect that interferes with pruning (Berk & Meyers, 2016; Bransford, Brown, & Cocking, 2000; Broderick & Blewitt, 2015).

Two kinds of overproduction and pruning processes take place. One is called *experience-expectant* because synapses are overproduced in certain parts of the brain during specific developmental periods, awaiting (expecting) stimulation. For example, during the first months of life, the brain expects visual and auditory stimulation. If a normal range of sights and sounds occurs, then the visual and auditory areas of the brain develop. But children who are born completely deaf receive no auditory stimulation and, as a result, the auditory processing area of their brains becomes devoted to processing visual information. Similarly, the visual processing area of the brain for children blind from birth becomes devoted to auditory processing (C. A. Nelson, 2001; Neville, 2007).

Experience-expectant overproduction and pruning processes are responsible for general development in large areas of the brain and may explain why adults have difficulty with pronunciations that are not part of their native language. For example, the distinction between the sounds of *r* and *l* is important in English but not in Japanese, so by about 10 months of age, Japanese infants lose the ability to discriminate between *r* and *l*; *those neurons are pruned away*. As a result, Japanese adults learning these sounds require intense instruction and practice. Just think about the cognitive advantages and extra capacities of an infant growing up learning two languages (Broderick & Blewitt, 2015; Hinton, Miyamoto, & Della-Chiesa, 2008).

The second kind of synaptic overproduction and pruning is called *experience-dependent*. Here, synaptic connections are formed based on the individual's experiences. New synapses are formed in response to neural activity in very localized areas of the brain. Examples are learning to ride a bike or use a spreadsheet. The brain does not "expect" these behaviors, so new synapses form in response to these experiences. Again, more

synapses are produced than will be kept after “pruning.” Experience-dependent processes are involved in individual learning, such as mastering unfamiliar sound pronunciations in a second language you are studying.

Stimulating environments may help in the pruning process in early life (experience-expectant period) and also may support increased synapse development in adulthood (experience-dependent period) (Broderick & Blewitt, 2015; J. L. Cook & Cook, 2014). In fact, animal studies have shown that rats raised in stimulating environments (with toys, tasks for learning, other rats, and human handling) develop and retain 25% more synapses than rats who are raised with little stimulation. Even though the research with rats may not apply directly to humans, it is clear that extreme deprivation can have negative effects on human brain development. But extra stimulation will not necessarily improve development for young children who are already getting adequate or typical amounts (Berk & Meyers, 2016; Byrnes & Fox, 1998). So spending money on expensive toys or baby education programs probably offers more stimulation than is necessary, and might be harmful. Pots and pans, blocks and books, sand and water all provide excellent, appropriate stimulation—especially if accompanied by caring conversations with parents or teachers.

Look back at Figure 2.2. It appears that there is nothing between the neurons but air. Actually, that is incorrect. The spaces are filled with **glial cells**, the *white matter* of the brain. There are trillions of these cells; they greatly outnumber neurons. Glial cells appear to have many functions, such as fighting infections, controlling blood flow and communication among neurons, and providing the *myelin* coating (see Figure 2.2) around axon fibers. **Myelination**, the coating of axon neuron fibers with an insulating fatty glial covering, influences thinking and learning. This process is something like coating bare electrical wires with rubber or plastic. This myelin coating makes message transmission faster and more efficient. Myelination happens quickly in the early years but continues gradually into adolescence, with the child’s brain doubling in volume in the first year of life and doubling again around puberty (J. R. Anderson, 2015; Ormrod, 2016).

The Developing Brain: Cerebral Cortex

Let’s move from the neuron level to the brain itself, which amazingly is almost 80% water, with the rest being fat and protein (Schunk, 2016). The outer 1/8-inch-thick covering is the cerebral cortex—the largest area of the brain. It is a thin sheet of neurons, but it is almost 3 square feet in area for adults. To get all that area in your head, the sheet is crumpled together with many folds and wrinkles (J. R. Anderson, 2015). In humans, this area of the brain is much larger than it is in lower animals. The cerebral cortex accounts for about 85% of the brain’s weight in adulthood and contains the greatest number of neurons. The cerebral cortex allows the greatest human accomplishments, such as complex problem solving and language.

The cortex is the last part of the brain to develop, so it is believed to be more susceptible to environmental influences than other areas of the brain (Gluck, Mercado, & Myers, 2016). Parts of the cortex mature at different rates. The region of the cortex that controls physical motor movement matures first, then the areas that control complex senses such as vision and hearing, and last, the frontal lobe that controls higher-order thinking processes. The temporal lobes of the cortex that play major roles in emotions, judgment, and language do not develop fully until the high school years and maybe later.

Different areas of the cortex seem to have distinct functions, as shown in Figure 2.3. Even though different functions are found in particular areas of the brain, these specialized functions are quite specific and elementary. To accomplish more complex functions such as speaking or reading, the various areas of the cortex must communicate and work together (J. R. Anderson, 2015).

Another aspect of brain functioning that has implications for cognitive development is **lateralization**, or the specialization of the two hemispheres of the brain. We know that each half of the brain controls the opposite side of the body. Damage to the right side of the brain will affect movement of the left side of the body and vice versa. In addition, certain areas of the brain affect particular behaviors. For most of us, the left hemisphere of the brain is a major factor in language processing, and the right hemisphere handles

Glial cells The *white matter* of the brain. These cells greatly outnumber neurons and appear to have many functions such as fighting infections, controlling blood flow and communication among neurons, and providing the *myelin* coating around axon fibers.

Myelination The process by which neural fibers are coated with a fatty sheath called *myelin* that makes message transfer more efficient.

Lateralization The specialization of the two hemispheres (sides) of the brain cortex.

FIGURE 2.3**A VIEW OF THE CEREBRAL CORTEX**

This is a simple representation of the left side of the human brain, showing the cerebral cortex. The cortex is divided into different areas, or lobes, each having a variety of regions with different functions. A few of the major functions are indicated here.

much of our spatial-visual information and emotions (nonverbal information). For some left-handed people, the relationship may be reversed, but for most left-handers, and for females on average, there is less hemispheric specialization altogether (J. R. Anderson, 2015; Ormrod, 2016). The brains of young children show more plasticity (adaptability) because they are not as specialized or lateralized as the brains of older children and adults. Young children with damage to the left side of the brain are somewhat able to overcome the damage, which allows language development to proceed. Different areas of the brain take over the functions of the damaged area. But in older children and adults, this compensation is less likely to occur after damage to the left hemisphere.

These differences in performance by the brain's hemispheres, however, are more relative than absolute; one hemisphere is just more efficient than the other in performing certain functions. Language is processed “differently, but simultaneously” by the left and right hemispheres (Alferink & Farmer-Dougan, 2010, p. 44). Nearly any task, particularly the complex skills and abilities that concern teachers, requires simultaneous participation of many different areas of the brain in constant communication with each other. For example, the left side of the brain is where grammar and syntax are understood, but the right side is better at figuring out the meaning of a story or interpreting sarcasm, irony, metaphors, or puns, so both sides of the brain have to work together in reading or making sense of literature, films, and jokes. Remember, no mental activity is exclusively the work of a single part of the brain, so there is no such thing as a “right-brained student” unless that individual has had the left hemisphere removed—a rare and radical treatment for some forms of epilepsy (Ormrod, 2016).

Brain Development in Childhood and Adolescence

The brain continues to develop throughout childhood and adolescence. In infancy, children identify patterns in their world and in the language(s) spoken by the people who care for them. Infants learn—form neural connections and networks—by exploring, acting, and observing. They are self-directed in this adventure—a good thing because they have so much to learn. During this time a stimulating, responsive, and safe environment is a much better “teacher” than flashcards or structured lessons because young children follow their own interests and curiosities.

In the elementary school years, children's brains continue to grow. The different parts of the brain that support various processes such as perception, memory, and emotion become more networked and connected. These interconnections enable children to reflect on their feelings and thoughts—to think about their own thinking. Children also can add to their store of knowledge and hold more information in memory at one time. At this age they are ready to learn more vocabulary and grammar in their first language and also to learn a second language. But they still have limited attention spans, so longer lessons, activities, or directions should be divided into manageable and memorable pieces (McDevitt & Ormrod, 2016). In addition, all of the ideas in Chapter 11 for developing self-regulated learning can support elementary school students as their growing brains open new possibilities for understanding and controlling their own cognitive processes.

During adolescence, changes in the brain increase individuals' abilities to control their behavior in both low-stress and high-stress situations, to be more purposeful and organized, and to inhibit impulsive behavior (Wigfield et al., 2006). But these abilities are not fully developed until the early twenties, so adolescents may "seem" like adults, at least in low-stress situations, but their brains are not mature. They often have trouble avoiding risks and controlling impulses. This is why adolescents' brains have been described as "high horse power, poor steering" (Organisation for Economic Co-operation and Development [OECD], 2007, p. 6).

One explanation for this problem with avoiding risks and impulsive behavior looks to differences in the pace of development for two key components of the brain—the limbic system and the prefrontal cortex of the brain (Casey, Getz, & Galvan, 2008). The limbic system develops earlier; it is involved with emotions and reward-seeking/novelty/risk-taking/sensation-seeking behaviors. The prefrontal lobe takes more time to develop; it is involved with judgment and decision making. As the limbic system matures, adolescents become more responsive to pleasure seeking and emotional stimulation. In fact, adolescents appear to need more intense emotional stimulation than either children or adults, so these young people are set up for taking risks and seeking thrills. Risk taking and novelty seeking can be positive factors for adolescent development as young people courageously try new ideas and behaviors—and learning is stimulated (Luna, Paulsen, Padmanabhan, & Geier, 2013). But their less mature prefrontal lobe is not yet good at saying, "Whoa—that thrill is too risky!" So in emotional situations, thrill seeking wins out over caution, at least until the prefrontal lobe catches up and becomes more integrated with the limbic system toward the end of adolescence. Then risks can be evaluated in terms of long-term consequences, not immediate thrills (Casey et al., 2008; D. G. Smith, Xiao, & Bechara, 2012). In addition, there are individual differences: Some adolescents are more prone than others to engage in risky behaviors.

Teachers can take advantage of their adolescent students' intensity by helping them devote their energy and passion to areas such as politics, the environment, public service, or social causes (L. F. Price, 2005) or by guiding them to explore emotional connections with characters in history or literature. Connections to family, school, community, and positive belief systems help adolescents "put the brakes" on reckless and dangerous behaviors (McAnarney, 2008).

Other changes in the neurological system during adolescence affect sleep; teenagers need about 9 hours of sleep per night, but many students' biological clocks are reset, making it difficult for them to fall asleep before midnight. Some experts interviewed by Sumathi Reddy (2014) have recommended that ideally high school should start at 9:00 or even 10:00 in the morning—sounds good to me! Yet in many school districts, high school begins by 7:30, which makes 9 hours of sleep impossible to get, so students are continually sleep deprived. Research in neuroscience shows that sleep deprivation impairs the initial formation of memories for facts, so learning suffers. This means that losing sleep to cram for tests actually interferes with learning by shutting down the very parts of the brain needed to remember what you are studying (Scalise & Felde, 2017). Classes that keep students in their seats taking notes for the full period may literally "put the students to sleep." With no time for breakfast and little for lunch, these students' nutritional needs are often deprived as well (Sprenger, 2005).

TABLE 2.2 • Myths About the Brain

COMMON MYTHS	TRUTH
1. You use only 10% of your brain. 2. Listening to Mozart will make children smarter. 3. Some people are more “right brained,” and others are more “left brained.” 4. A young child’s brain can only manage to learn one language at a time. 5. You can’t change your brain. 6. Damage to the brain is permanent. 7. Playing games like Sudoku keeps your brain from aging. 8. The human brain is the biggest brain. 9. Alcoholic beverages kill brain cells. 10. The adolescent’s brain is the same as that of an adult.	1. You use all your brain. That is why strokes are so devastating. 2. Listening won’t, but learning to play a musical instrument is associated with increased cognitive achievement. 3. It takes both sides of your brain to do most things. 4. Children all over the world can and do learn two languages at once. 5. Our brains are changing all the time. 6. Most people recover well from minor brain injuries. 7. Playing Sudoku makes you better at playing Sudoku and similar games. Physical exercise is a better bet to prevent decline. 8. Sperm whales have brains five times heavier than those of humans. 9. Heavy drinking does not kill brain cells, but it can damage the nerve ends called dendrites, and this causes problems with communicating messages in the brain. This damage is mostly reversible. 10. There are critical differences between adolescents’ and adults’ brains, especially in the areas of judgment and risk assessment.

Putting It All Together: How the Brain Works

What is your conception of the brain? Is the brain a culture-free container that holds knowledge the same way for everyone? Is the brain like a library of facts or a computer filled with information? Do you wake up in the morning, download what you need for the day, and then go merrily on your way? Is the brain like a pipe that transfers information from one person to another—a teacher to a student, for example? Kurt Fischer—a developmental psychologist and Harvard professor—offers a different view, based on neuroscience research. Knowing is actively constructing understandings and actions. Knowledge is based in our activities, and the brain is constantly changing. Experience “sculpts the way that our brains work, changing neurons, synapses, and brain activity” (Fischer, 2009, p. 5). See Table 2.2 for some other myths and truths about the brain.

CULTURE AND BRAIN PLASTICITY. All experiences sculpt the brain—play and deliberate practice, formal and informal learning (Dubinsky et al., 2013). You encountered the term earlier that describes the brain’s capacity for constant change in neurons, synapses, and activity—*plasticity*. Cultural differences in brain activity provide examples of how interactions in the world shape the brain through plasticity. For example, in one study, when Chinese speakers added and compared Arabic numbers, they showed brain activity in the motor (movement) areas of their brains, whereas English speakers performing the same tasks had activity in the language areas of their brains (Tang et al., 2006). One explanation is that Chinese children are taught arithmetic using an abacus—a calculation tool that involves movement and spatial positions. As adults, these children retain a kind of visual-motor sense of numbers (Varma, McCandliss, & Schwartz, 2008). There also are cultural differences in how languages affect reading. For example, when they read, native Chinese speakers activate additional parts of their brain associated with spatial information processing, probably because the language characters used in written Chinese are pictures. But Chinese speakers also activate these spatial areas of the brain when they read English, demonstrating that reading proficiency can be reached through different neural pathways (Hinton, Miyamoto, & Della-Chiesa, 2008). So thanks to plasticity, the brain is ever changing, shaped by activity, culture, and context. We build knowledge as we do things, as we manipulate objects and ideas mentally and physically.

As you can imagine, educators have looked for applications of neuroscience research for their instruction. We turn to this next.

POINT/COUNTERPOINT: Brain-Based Education

Educators are hearing more and more about brain-based education. Are there clear educational implications from the neuroscience research on the brain?

POINT

No, the implications are not clear. John Bruer, president of the James S. McDonnell Foundation, has written articles that are critical of the brain-based education craze (Bruer, 1999, 2002). He notes that many so-called applications of brain research begin with solid science, but then move to unwarranted speculation, and end in a sort of appealing folk tale about the brain and learning. He suggests that for each claim, the educator should ask, “Where does the science end and the speculation begin?” One claim that Bruer questions is the notion of right-brain, left-brain learning, a popular idea that has been around for over 30 years, even though neuroscientists keep debunking the claims. For example, in his book for educators, *How the Brain Learns*, David Sousa suggests that teachers have students engage their “right brains” by generating and using mental imagery. Even though different brain areas are specialized for different tasks, this specialization occurs at very fine levels of analysis, and forming visual images involves many parts of the brain. As we will see later in this book, imagery can be a good learning strategy but not because it enlists the “underutilized” right brain in learning (Bruer, 1999). Kurt Fischer (2009), president of

the International Mind, Brain, and Education Society, has lamented that many *neuromyths* like those in Table 2.2—blatantly wrong beliefs about how the brain and body work—still are widely accepted.

No teacher doubts that the brain is important in learning. As Steven Pinker (2002), professor of psychology at Harvard University, observed, does anyone really think learning takes place somewhere else, like the pancreas? But knowing that learning affects the brain does not tell us how to teach. All learning affects the brain; “this should be obvious, but nowadays any banality about learning can be dressed up in neurospeak and treated like a great revelation of science” (Pinker, 2002, p. 86). Virtually all of the so-called best practices for brain-based education are simple restatements of good teaching based on understandings of how people learn, not how their brains work. For example, we have known for over 100 years that it is more effective to learn in many shorter practice sessions as opposed to one long cramming session. To tie that fact to building more dendrites may give one reason why the strategy works, but it does not offer teachers new strategies (Alferink & Farmer-Dougan, 2010).

MyLab Education
Podcast 2.1

Listen as textbook author Anita Woolfolk talks about brain-based education. What does this mean? Are there some clear implications for teachers or is it still too early to say?

Neuroscience, Learning, and Teaching

There has been vigorous debate between the enthusiastic educational advocates of brain-based education and the skeptical neuroscience researchers who caution that studies of the brain do not really address major educational questions yet. See the *Point/Counterpoint* for a slice of this debate.

DOES INSTRUCTION AFFECT BRAIN DEVELOPMENT? There are differences in brain activity associated with instruction. For example, the intensive instruction and practice provided to rehabilitate stroke victims can help them regain functioning by forming new connections and using new areas of the brain (Bransford, Brown, & Cocking, 2000; McKinley, 2011). In a dramatic example of how teaching can affect brain development, K. W. Fischer (2009) describes two children who each had one brain hemisphere removed as a treatment for severe epilepsy. Nico’s right hemisphere was removed when he was 3, and his parents were told he would never have good visual-spatial skills. With strong and constant support and teaching, Nico grew up to be a skilled artist! Brooke’s left hemisphere was removed when he was 11. His parents were told he would lose his ability to talk. Again, with strong support, he regained enough speaking and reading ability to finish high school and attend community college.

THE BRAIN AND LEARNING TO READ. Brain imaging research is revealing interesting differences among skilled and less-skilled readers as they learn new vocabulary. For example, one imaging study showed that less-skilled readers had trouble establishing high-quality representations of new vocabulary words in their brains, as indicated by

Yes, teaching should be brain-based. Articles in popular magazines such as *Newsweek* assert, “. . . it’s naive to say that brain discoveries have no consequences for understanding how humans learn” (Begley, 2007). Do scientists agree? In their article on “Applying Cognitive Neuroscience Research to Education” in the *Educational Psychologist*, Tami Katzir and Juliana Paré-Blagoev (2006) concluded, “When applied correctly, brain science may serve as a vehicle for advancing the application of our understanding of learning and development. . . . Brain research can challenge common-sense views about teaching and learning by suggesting additional systems that are involved in particular tasks and activities” (p. 70). If we are to guard against overstating the links between brain research and education, then we should not ask *whether* to teach neuroscience to preservice teachers, but instead, *how best* to do that teaching (Dubinsky et al., 2013). A number of universities, including Harvard, Cambridge, Dartmouth, the University of Texas at Arlington, University of Minnesota, University of Southern California, Beijing Normal University, Southeast University in Nanjing, and Johns Hopkins are pioneering this process. They have established training programs for educators in brain-education studies (Dubinsky et al., 2013; K. Fischer, 2009; Wolfe, 2010). Other educational psychologists have called for a new professional specialty—neuro-educators (Beauchamp & Beauchamp, 2013).

A reading improvement product called *FastForward* was developed by two neuroscientists, Dr. Michael Merzenich and Dr. Paula Tallal, and is already in use today in classrooms around the country (see www.scilearn.com/results/success-stories/

case-studies). It specifically uses discoveries in neural plasticity to change the brain’s ability to read the printed word (Tallal & Miller, 2003).

In his presidential address for the First Conference of the International Mind, Brain, and Education Society, Kurt Fischer (2009) also noted that the primary goal of that organization is to ground education in solid research from biology, cognitive science, development, and education while avoiding myths and popular misconceptions. Fischer makes the point that we can go from understanding how the brain works to understanding cognitive processes, and then to developing educational practices. But jumping directly from knowledge about the brain to educational practices probably involves too much speculation.

Beware of Either/Or. The application of neuroscience to education actually has been plagued by *misapplications* because educators and neuroscience researchers have different meanings for the concept of *learning*; few educators have a background in neurobiology and most neuroscientists can’t create concrete and useful applications of research on the brain because they just don’t know enough about the specifics of teaching in kindergarten to high school classrooms (Beauchamp & Beauchamp, 2013). However, to ignore what we do know about the brain would be irresponsible. Brain-based learning offers some direction for educators who want more purposeful, informed teaching. At the very least, the neuroscience research is helping us to understand why effective teaching strategies, such as distributed practice, work. The person in the best position to create, invent, and apply strategies is a teacher who understands both the way the brain works and how children learn (Scalise & Felde, 2017).

Resources: Podcast on understanding the brain: <http://www.oecd.org/edu/ceeri/understandingthebrainthebirthofalearningscience.htm>

ERP measurements of electrical activity of the brain. When they encountered one of the new words later, less-skilled readers’ brains often didn’t recognize that they had seen the word before, even though they had learned it in an earlier lesson. If words you have learned previously seem unfamiliar later, you can see how it would be hard to understand what you read (Balass, Nelson, & Perfetti, 2010).

Reading is not innate or automatic—every brain has to be taught to read (Frey & Fisher, 2010). Reading is a complex integration of the systems in the brain that recognize sounds, written symbols, meanings, and sequences, and then connect with what the reader already knows. This has to happen quickly and automatically (Wolf et al., 2009). What are some strategies suggested? Use multiple approaches that teach sounds, spelling, meanings, sequencing, and vocabulary through reading, writing, discussing, explaining, drawing, and modeling. Different students may learn in different ways, but all need practice in literacy.

EMOTIONS, LEARNING, AND THE BRAIN. Finally, another clear connection between the brain and classroom learning is in the area of emotions and stress. Let’s step inside a high school math classroom described by Hinton, Miyamoto, and Della-Chiesa (2008, p. 91) for an example:

Patricia, a high school student, struggles with mathematics. The last few times she answered a mathematics question she got it wrong and felt terribly embarrassed, which formed an association between mathematics . . . and negative emotions. . . . Her teacher had just asked her to come to the blackboard to solve a problem. This caused an immediate transfer of this emotionally-charged association to the amygdala, which elicits fear. Meanwhile, a slower, cortically-driven cognitive appraisal of the situation

is occurring: she remembers her difficulty completing her mathematics homework last night, notices the problem on the board contains complicated graphs, and realizes that the boy she has a crush on is watching her from a front-row seat. These various thoughts converge to a cognitive confirmation that this is a threatening situation, which reinforces her progressing fear response and disrupts her ability to concentrate on solving the mathematics problem.

In Chapter 7 you will learn about how emotions can become paired with particular situations; and in Chapter 12, you will see that anxiety interferes with learning, whereas challenge, interest, and curiosity can support learning. If students feel unsafe and anxious, they are not likely to be able to focus attention on academics (Sylvester, 2003). But if students are not challenged or interested, learning suffers too. Keeping the level of challenge and support “just right” is a challenge for teachers. And helping students learn to regulate their own emotions and motivation is an important goal for education (see Chapter 11). Simply put, learning will be more effective “if educators help to minimize stress and fear at school, teach students emotional regulation strategies, and provide a positive learning environment that is motivating to students” (Hinton, Miyamoto, & Della-Chiesa, 2008).

STOP & THINK As a teacher, you don’t want to fall for overly simplistic “brain-based” teaching slogans. But obviously, the brain and learning are intimately related—this is not a surprise. So how can you be a savvy, “neuroscientific” teacher (Murphy & Benton, 2010)? •

Lessons for Teachers: General Principles

What can we learn from neuroscience? One overarching idea is that teachers and students should transform the notion of learning from “using your brain” to “changing your brain”—embrace the amazing plasticity of the brain (Dubinsky et al., 2013). Here are some general teaching implications drawn from Brown, Roedinger, and McDaniel (2014), Driscoll (2005), Dubinsky and colleagues (2013), Murphy and Benton (2010), Sprenger (2010), Scalise and Felde (2017), and Wolfe (2010):

1. Human capabilities—intelligence, communication, problem solving, and so on—emerge from each person’s unique synaptic activity overlaid on his or her genetically endowed brain anatomy; nature and nurture are in constant activity together. The brain can place some limits on learning in the form of genetic brain anomalies in neural wiring or structure, but learning can occur through alternate pathways in the brain (as Nico and Brooke demonstrate). So, *there are multiple ways both to teach and to learn a skill*, depending on the student.
2. *Many cognitive functions are differentiated*; they are associated with different parts of the brain. Using a range of modalities for instruction and activities that draw on different senses may support learning—for example, using maps and songs to teach geography. Using different modalities also helps students stay focused and engaged. Assessment should be differentiated, too.
3. *The brain is relatively plastic*, so enriched, active environments and flexible instructional strategies are likely to support cognitive development in young children and learning in adults. The brain is constantly changing at many levels from cells to connections to remapping skills in new areas in response to an injury—think plasticity!
4. *Changing the brain takes time*, so teachers must be consistent, patient, and compassionate in teaching and reteaching in different ways, as Nico’s and Brooke’s parents and teachers could tell you. Don’t overwhelm the brain with a heavy cognitive load (see Chapter 8) that presents too much too fast. Give students ways of managing the cognitive load using graphic organizers, visuals, tables, glossaries, notes, and other “external brain” tools.
5. *Some learning disorders may have a neurological basis*; neurological testing may assist in diagnosing and treating these disorders, as well as in evaluating the effects of various treatments.
6. Learning from *real-life problems and concrete experiences* helps students construct knowledge and also gives them multiple pathways for learning and retrieving

information. Knowledge learned should be clearly connected with situations in which it is useful. “Inert” knowledge that is memorized but not used is quickly forgotten.

7. *The brain seeks meaningful patterns and connections with existing networks*, so teachers should tie new information to what students already understand and help them form new connections. Use both concrete and abstract examples where possible and ask students to think of their own examples. Information that is not linked to existing knowledge will be easily forgotten. Help students recognize patterns by pointing out similarities and differences and teaching how to detect patterns.
8. Because the brain naturally looks for patterns and makes predictions about what to expect, *feedback is critical*, because feedback is a form of evidence to help the brain correct and improve its predictions.
9. *It takes a long time and extensive practice to build and consolidate knowledge*. Numerous visits and practice in different contexts and distributed over time (not all at once) help to form strong, multiple connections. Changing the brain (learning) benefits from elaborating, extending, and applying concepts in different situations and subjects over time. Probing questions, worked out examples, annotated and carefully labeled charts and graphs, reflection, and asking students to explain new learning to themselves and each other all help.
10. *Large, general concepts should be emphasized over small specific facts* so students can build enduring, useful knowledge categories and associations that are not constantly changing.
11. *Stories should be used in teaching*. Stories engage many areas of the brain—memories, experiences, feelings, and beliefs. Stories also are organized and have a sequence—beginning, middle, end—so they are easier to remember than unrelated or unorganized information.
12. *Emotions and health affect learning*—positive emotions can support learning and memory, whereas negative emotions can interfere. Emotions also are related to motivation, as you will see in Chapter 12. Stress, lack of sleep, poor nutrition, and lack of exercise all can affect the brain’s ability to learn.
13. Helping students understand how activity (distributed practice, problem solving, making connections, inquiry, etc.) changes their brain and how emotions and stress affect attention and memory can be motivating, leading to greater self-efficacy and self-regulated learning (we talk more about this in Chapter 11). One important message to students is that *they are responsible for doing what it takes to change their own brains; they have to work (and play) to learn*.

For the rest of the chapter, we turn from the brain and cognitive development to examine several major theories of cognitive development, the first offered by a biologist turned psychologist, Jean Piaget.

MyLab Education [Self-Check 2.2](#)

PIAGET’S THEORY OF COGNITIVE DEVELOPMENT

Swiss psychologist Jean Piaget was a real prodigy. In fact, in his teens, he published so many scientific papers on mollusks (marine animals such as oysters, clams, octopuses, snails, and squid) that he was offered a job as the curator of the mollusk collection at the Museum of Natural History in Geneva. He told the museum officials that he wanted to finish high school first. For a while, Piaget worked in Alfred Binet’s laboratory in Paris developing intelligence tests for children. The reasons children gave for their wrong answers fascinated him, and this prompted him to study the thinking behind their answers. This question intrigued him for the rest of his life (Green & Piel, 2010). He continued to write until his death at the age of 84 (P. H. Miller, 2016).

During his long career, Piaget devised a model describing how humans go about making sense of their world by gathering and organizing information (Piaget, 1954,

1963, 1970a, 1970b). We will examine Piaget's ideas closely, because they provide an explanation of the development of thinking from infancy to adulthood.

PUT YOURSELF IN A CHILD'S PLACE Can you be in Pittsburgh, Pennsylvania, and in the United States at the same time? Is this a difficult question for you? How long did it take you to answer? •

According to Piaget (1954), certain ways of thinking that are quite simple for an adult, such as the Pittsburgh question in *Stop & Think*, are not so straightforward for a child. For example, do you remember the 9-year-old child at the beginning of the chapter who was asked if he could be a Genevan? He answered, “No, *that's not possible. I'm already Swiss. I can't also be Genevan*” (Piaget, 1965/1995, p. 252). Imagine teaching this student geography. He has trouble with classifying one concept (Geneva) as a subset of another (Switzerland). There are other differences between adult and child thinking, too. Children's concepts of time may be different from your own. They may think, for example, that they will some day catch up to a sibling in age, or they may confuse the past and the future. Let's examine why.

Influences on Development

Cognitive development is much more than the addition of new facts and ideas to an existing store of information. According to Piaget, our thinking processes change radically, though slowly, from birth to maturity because we constantly strive to make sense of the world. Piaget identified four factors—biological maturation, activity, social experiences, and equilibration—that interact to influence changes in thinking (Piaget, 1970a). *Maturation* is the unfolding of the biological changes that are genetically programmed. Parents and teachers have little impact on this aspect of cognitive development, except to be sure that children get the nourishment and care they need to be healthy. With physical maturation comes the increasing ability to act on the environment and learn from it. When a young child's coordination is reasonably developed, for example, the child can discover principles about balance by walking on a low balance beam. Thus, *activity*—exploring, testing, observing, and eventually organizing information—changes our thinking processes. Our cognitive development also is influenced by *social transmission*, or learning from others. Without social transmission, we would need to reinvent all the knowledge already offered by our culture. The amount people can learn from social transmission varies according to their stage of cognitive development. We'll return to a discussion of the fourth influence on thinking, *equilibration*, in the next section.

Maturation, activity, and social transmission all work together to influence cognitive development. How do we respond to these influences?

Basic Tendencies in Thinking

As a result of his early research in biology, Piaget concluded that all species inherit two basic tendencies, or “invariant functions.” The first of these tendencies is toward **organization**—the combining, arranging, recombining, and rearranging of behaviors and thoughts into coherent systems. The second tendency is toward **adaptation**, or adjusting to the environment.

Organization Ongoing process of arranging information and experiences into mental systems or categories. Ordered and logical network of relations.

Adaptation Adjustment to the environment.

ORGANIZATION. People are born with a tendency to organize their thinking processes into psychological structures—systems for understanding and interacting with the world. Simple structures are continually combined and coordinated to become more sophisticated and thus more effective. Very young infants, for example, can either look at an object or grasp it when it comes in contact with their hands. They cannot coordinate looking and grasping at the same time. As they develop, however, infants organize these two separate behavioral structures into a coordinated higher-level structure of looking

at, reaching for, and grasping the object. They can, of course, still use each structure separately (Flavell, Miller, & Miller, 2002; P. H. Miller, 2016).

Piaget gave a special name to these psychological structures: **schemes**. In his theory, schemes are the basic building blocks of thinking. They are organized systems of actions or thought that allow us to mentally represent or “think about” the objects and events in our world. Schemes can be very small and specific—for example, the sucking-through-a-straw scheme or the recognizing-a-rose scheme. Or they can be larger and more general—for example, the drinking scheme or the gardening scheme.

ADAPTATION. In addition to the tendency to organize psychological structures, people also inherit the tendency to adapt to their environment. Two basic processes are involved in adaptation: assimilation and accommodation.

Assimilation involves trying to understand something new by fitting it into what we already know—by using our existing schemes. At times, we may have to distort the new information to make it fit. For example, the first time many children see a raccoon, they call it a “kitty.” They try to match the new experience with an existing scheme for identifying animals.

Accommodation occurs when we must change existing schemes to respond to a new situation. If we cannot make new data fit any existing schemes, then we must develop more appropriate structures. We adjust our thinking to fit the new information, instead of adjusting the information to fit our thinking. Children demonstrate accommodation when they add the scheme for recognizing raccoons to their other systems for identifying animals.

People adapt to their increasingly complex environments by using existing schemes whenever these schemes work (assimilation) and by modifying and adding to their schemes when something new is needed (accommodation). In fact, both processes are required most of the time. Even using an established pattern such as sucking through a straw requires some accommodation if the straw is of a different size or length than the type you are used to. If you have tried drinking juice from box packages, you know that you have to add a new skill to your sucking-through-a-straw scheme: Don’t squeeze the box or you will shoot juice through the straw, straight up into the air and into your lap. Whenever new experiences are assimilated into an existing scheme, the scheme is enlarged and changed somewhat, so assimilation involves some accommodation (Mascolo & Fischer, 2005).

There are also times when neither assimilation nor accommodation is used. If people encounter something that is too unfamiliar, they may ignore it. Experience is filtered to fit the kind of thinking a person is doing at a given time. For example, if you overhear a conversation in a foreign language, you probably will not try to make sense of the exchange unless you have some knowledge of the language.

EQUILIBRATION. According to Piaget, organizing, assimilating, and accommodating can be viewed as a kind of complex balancing act. In his theory, the actual changes in thinking take place through the process of **equilibration**—the act of searching for a balance. Piaget assumed that people continually test the adequacy of their thinking processes in order to achieve that balance. Briefly, the process of equilibration works like this: If we apply a particular scheme to an event or situation and the scheme works, then equilibrium exists. If the scheme does not produce a satisfying result, then **disequilibrium** exists, and we become uncomfortable. This motivates us to keep searching for a solution through assimilation and accommodation, and thus our thinking changes and moves ahead. Of course, the level of disequilibrium must be just right or optimal—too little and we aren’t interested in changing, too much and we may be discouraged or anxious and not change.

Four Stages of Cognitive Development

Now we turn to the actual differences that Piaget hypothesized for children as they grow. Piaget believed that all people pass through the same four stages in exactly the same order. The stages are generally associated with specific ages, but these are only general guidelines, not labels for all children of a certain age. Piaget noted that individuals may go through long periods of transition between stages and that a person may show

MyLab Education
Video Example 2.1

The children in this video are learning something new about growth by observing a tadpole as it changes from day to day. They can assimilate the idea that the tadpole grows legs, but they need to accommodate their concept of growth to understand why the tadpole’s tail gets smaller.

Schemes Mental systems or categories of perception and experience.

Assimilation Fitting new information into existing schemes.

Accommodation Altering existing schemes or creating new ones in response to new information.

Equilibration Search for mental balance between cognitive schemes and information from the environment.

Disequilibrium In Piaget’s theory, the “out-of-balance” state that occurs when a person realizes that his or her current ways of thinking are not working to solve a problem or understand a situation.

TABLE 2.3 • Piaget's Stages of Cognitive Development

STAGE	APPROXIMATE AGE	CHARACTERISTICS
Sensorimotor	0–2 years	Learns through reflexes, senses, and movement—actions on the environment. Begins to imitate others and remember events; shifts to symbolic thinking. Comes to understand that objects do not cease to exist when they are out of sight—object permanence. Moves from reflexive actions to intentional activity.
Preoperational	Begins about the time the child starts talking, to about 7 years old	Develops language and begins to use symbols to represent objects. Has difficulty with past and future—thinks in the present. Can think through operations logically in one direction. Has difficulties understanding the point of view of another person.
Concrete Operational	Begins about first grade, to early adolescence, around 11 years old	Can think logically about concrete (hands-on) problems. Understands conservation and organizes things into categories and in series. Can reverse thinking to mentally “undo” actions. Understands past, present, and future.
Formal Operational	Adolescence to adulthood	Can think hypothetically and deductively. Thinking becomes more scientific. Solves abstract problems in logical fashion. Can consider multiple perspectives and develops concerns about social issues, personal identity, and justice.

characteristics of one stage in one situation, but traits of a higher or lower stage in other situations. Therefore, remember that knowing a student's age is never a guarantee you will know how the child thinks (Orlando & Machado, 1996). Table 2.3 summarizes the stages.

INFANCY: THE SENSORIMOTOR STAGE. The earliest period is called the **sensorimotor** stage, because the child's thinking involves seeing, hearing, touching, tasting, moving and so on. During this period, infants develop **object permanence**, the understanding that objects exist in the environment whether they perceive them or not. This is the beginning of the important ability to construct a mental representation. As most parents discover, before infants develop object permanence, it is relatively easy to take something away from them. The trick is to distract them and remove the object while they are not looking—“out of sight, out of mind.” The older infant who searches for the ball that has rolled out of sight is indicating an understanding that objects still exist even when they are not in view (M. K. Moore & Meltzoff, 2004).

A second major accomplishment in the sensorimotor period is the beginning of logical, **goal-directed actions**. Think of the familiar clear plastic container baby toy with a lid and several colorful items inside that can be dumped out and replaced. A 6-month-old baby is likely to become frustrated trying to get to the toys inside. An older child who has mastered the basics of the sensorimotor stage will probably be able to deal with the toy in an orderly fashion by building a “container toy” scheme: (1) get the lid off, (2) turn the container upside down, (3) shake if the items jam, and (4) watch the items fall. Separate lower-level schemes have been organized into a higher-level scheme to achieve a goal.

The child is soon able to reverse this action by refilling the container. Learning to reverse actions is a basic accomplishment of the sensorimotor stage. As we will soon see, however, learning to reverse thinking—that is, learning to imagine the reverse of a sequence of actions—takes much longer.

Sensorimotor Involving the senses and motor activity.

Object permanence The understanding that objects have a separate, permanent existence.

Goal-directed actions Deliberate actions toward a goal.

EARLY CHILDHOOD TO THE EARLY ELEMENTARY YEARS: THE PREOPERATIONAL STAGE. By the end of the sensorimotor stage, the child can use many action schemes. However, as long as these schemes remain tied to physical actions, they are of no use in recalling the past, keeping track of information, or planning. For this, children need what Piaget called **operations**, or actions that are carried out and reversed *mentally* rather than physically. At the **preoperational** stage the child is moving toward mastery, but has not yet mastered these mental operations (so thinking is *preoperational*).

According to Piaget, the first type of thinking that is separate from action involves making action schemes symbolic. The ability to form and use symbols—words, gestures, signs, images, and so on—is thus a major accomplishment of the preoperational period and moves children closer to mastering the mental operations of the next stage. This ability to work with symbols to represent an object that is not present, such as using the word *horse* or a picture of a horse or even pretending to ride a broomstick horse, is called the **semiotic function**. In fact, the child's earliest use of symbols is in pretending—pretending to drink from an empty cup, showing that they know what the object is for. This behavior also shows that their schemes are becoming more general and less tied to specific actions. The drinking scheme, for example, can be used in playing house. During the preoperational stage, there is also rapid development of that very important symbol system, language. Between the ages of 2 and 4, most children enlarge their vocabulary from about 200 to 2,000 words.

As the child moves through the preoperational stage, the developing ability to think about objects in symbolic form remains somewhat limited to thinking in one direction only, or using one-way logic. It is very difficult for the child to “think backward,” or imagine how to reverse the steps in a task. **Reversible thinking** is involved in many tasks that are difficult for the preoperational child, such as the conservation of matter.

Conservation is the principle that the amount or number of something remains the same even if the arrangement or appearance is changed, as long as nothing is added and nothing is taken away. You know that if you tear a piece of paper into several pieces, you will still have the same amount of paper. To prove this, you know that you can reverse the process by taping the pieces back together, but a child using preoperational thinking can't think that way. Here is a classic example of difficulty with conservation. Leah, a 5-year-old, is shown two identical glasses, both short and wide in shape. Both have exactly the same amount of colored water in them. She agrees that the amounts are “the same.” The experimenter then pours the water from one of the glasses into a taller, narrower glass and asks, “Now, does one glass have more water, or are they the same?” Leah responds that the tall glass has more because “It goes up more here” (she points to the higher level on the taller glass). Piaget's explanation for Leah's answer is that she is focusing, or *centering*, attention on the dimension of height. She has difficulty considering more than one aspect of the situation at a time (height and width), or **decentering**. Thus, children at the preoperational stage have trouble freeing themselves from their own immediate perceptions of how the world appears.

This brings us to another important characteristic of the preoperational stage. Preoperational children, according to Piaget, have a tendency to be **egocentric**, to see the world and the experiences of others from their own viewpoint. This is one reason it is difficult for preoperational children to understand that *your* right hand is not on the same side as theirs when you are facing them. The concept of egocentrism, as Piaget intended it, does not mean selfish; it simply means children often assume that everyone else shares their feelings, reactions, and perspectives. For example, the 2-year-old at the beginning of this chapter who brought his own mother to comfort a distressed friend—even though the friend's mother was available—was simply seeing the situation through his own eyes and providing what he would want for his friend.

Research has shown that young children are not totally egocentric in every situation, however. Children as young as age 2 describe more details about a situation to a parent who was not present than they provide to a parent who experienced the situation with them. So young children do seem quite able to take the needs and different perspectives of others into account, at least in certain situations (Flavell et al., 2002). And in fairness to

MyLab Education
Video Example 2.2

In this video, children participate in tasks that show their understanding of conservation of volume and conservation of number. Compare the responses, and identify each child's stage of cognitive development, according to Piaget's theory.

Operations Actions a person carries out by thinking them through instead of literally performing the actions.

Preoperational The stage before a child masters logical mental operations.

Semiotic function The ability to use symbols—language, pictures, signs, or gestures—to represent actions or objects mentally.

Reversible thinking Thinking backward, from the end to the beginning.

Conservation Principle that some characteristics of an object remain the same despite changes in appearance.

Decentering Focusing on more than one aspect at a time.

Egocentric Assuming that others experience the world the way you do.

GUIDELINES

FAMILY AND COMMUNITY PARTNERSHIPS

Helping Families Care for Preoperational Children

Encourage families to use concrete props and visual aids whenever possible.

Examples

1. When family members use words such as *part*, *whole*, or *one half*, encourage them to demonstrate using objects in the house such as cutting an apple or pizza into parts.
2. Let children add and subtract with sticks, rocks, or colored chips. This technique also is helpful for early concrete-operational students.

Make instructions relatively short—not too many steps at once. Use actions as well as words.

Examples

1. When giving instructions such as how to feed a pet, first model the process, then ask the child to try it.
2. Explain a game by acting out one of the parts.

Help children develop their ability to see the world from someone else's point of view.

Examples

1. Ask children to imagine "how your sister felt when you broke her toy."

2. Be clear about rules for sharing or use of material. Help children understand the value of the rules, and work with them to develop empathy by asking them to think about how they would like to be treated. Avoid long lectures on "sharing" or being "nice."

Give children a great deal of hands-on practice with the skills that serve as building blocks for more complex skills such as reading comprehension or collaboration.

Examples

1. Provide cut-out letters or letter magnets for the refrigerator to build words.
2. Do activities that require measuring and simple calculations—cooking, dividing a batch of popcorn equally.

Provide a wide range of experiences in order to build a foundation for concept learning and language.

Examples

1. Take trips to zoos, gardens, theaters, and concerts; encourage storytelling.
2. Give children words to describe what they are doing, hearing, seeing, touching, tasting, and smelling.

Concrete operations

Mental tasks tied to concrete objects and situations.

Identity Principle that a person or object remains the same over time.

Compensation The principle that changes in one dimension can be offset by changes in another.

Reversibility

A characteristic of Piagetian logical operations—the ability to think through a series of steps, then mentally reverse the steps and return to the starting point; also called reversible thinking.

Classification Grouping objects into categories.

young children, even adults can make assumptions that others feel or think like they do—think about all the politicians who believe "the people agree with me!" The *Guidelines: Family and Community Partnerships* give ideas for working with preoperational thinkers and for guiding families in supporting the cognitive development of their children.

LATER ELEMENTARY TO THE MIDDLE SCHOOL YEARS: THE CONCRETE-OPERATIONAL STAGE. Piaget coined the term **concrete operations** to describe this stage of "hands-on" thinking. The basic characteristics of the stage are the recognition of the logical stability of the physical world; the realization that elements can be changed or transformed and still conserve many of their original characteristics; and the understanding that these changes can be reversed.

Look at Figure 2.4 to see examples of the different tasks given to children to assess conservation. According to Piaget, the ability to solve conservation problems depends on having an understanding of three basic aspects of reasoning: identity, compensation, and reversibility. With a complete mastery of **identity**, the student knows that if nothing is added or taken away, the material remains the same. With an understanding of **compensation**, the student knows that an apparent change in one direction can be compensated for by a change in another direction. That is, if the glass is narrower, the liquid will rise higher in the glass. And with an understanding of **reversibility**, the student can mentally cancel out the change that has been made. Leah apparently knew it was the same water (identity), but she lacked compensation and reversibility, so she was still moving toward conservation.

Another important operation mastered at this stage is **classification**. This operation depends on a student's abilities to focus on a single characteristic of objects in a set (e.g., color) and group the objects according to that characteristic. More advanced classification at this stage involves recognizing that one class fits into another. A city can be in a particular state or province and also in a particular country, as you probably

FIGURE 2.4

SOME PIAGETIAN CONSERVATION TASKS

In addition to the tasks shown here, other tasks involve the conservation of number, length, weight, and volume. These tasks are all achieved over the concrete-operational period.

	Suppose you start with this	→	Then you change the situation to this	→	The question you would ask a child is
(a) conservation of mass		Roll out clay ball B			Which is bigger, A or B?
(b) conservation of weight		Roll out clay ball B			Which will weigh more, A or B?
(c) conservation of volume		Take clay ball out of water and roll out clay ball B			When I put the clay back into the water beakers, in which beaker will the water be higher?
(d) conservation of continuous quantity		Pour water in beaker A into beaker C			Which beaker has more liquid, B or C?
(e) conservation of number		Break candy bar B into pieces			Which is more candy? A or B?

knew when I asked you earlier about Pittsburgh, Pennsylvania, USA. As children apply this advanced classification to locations, they often become fascinated with “complete” addresses such as Lee Jary, 5116 Forest Hill Drive, Richmond Hill, Ontario, Canada, North America, Northern Hemisphere, Earth, Solar System, Milky Way, Universe. Classification is also related to reversibility. The ability to reverse a process mentally allows the concrete-operational student to see that there is more than one way to classify a group of objects. The student understands, for example, that shapes can be classified by color, and then reclassified by size or by the number of sides.

Seriation is the process of making an arrangement of items in order from large to small or vice versa. This understanding of sequential relationships permits a student to construct a logical series in which $A < B < C$ (A is less than B is less than C) and so on. Unlike the preoperational child, the concrete-operational child can grasp the notion that B can be larger than A but still smaller than C.

Seriation Arranging objects in sequential order according to one aspect, such as size, weight, or volume.

GUIDELINES

Teaching the Concrete-Operational Child

Continue to use concrete props and visual aids, especially when dealing with sophisticated material.

Examples

1. Use timelines in history and three-dimensional models in science.
2. Use diagrams to illustrate hierarchical relationships such as branches of government and the agencies under each branch.

Continue to give students a chance to manipulate and test objects.

Examples

1. Set up simple scientific experiments such as the following involving the relationship between fire and oxygen. What happens to a flame when you blow on it from a distance? (If you don't blow it out, the flame gets larger briefly, because it has more oxygen to burn.) What happens when you cover the flame with a jar?
2. Have students make candles by dipping wicks in wax, weave cloth on a simple loom, bake bread, set type by hand, or do other craft work that illustrates the daily occupations of people in the colonial period.

Make sure presentations and readings are brief and well organized.

Examples

1. Assign stories or books with short, logical chapters, moving to longer reading assignments only when students are ready.
2. Break up a presentation, giving students an opportunity to practice the first steps before introducing the next steps.

Use familiar examples to explain more complex ideas.

Examples

1. Compare students' lives with those of characters in a story. After reading *Island of the Blue Dolphins* (the true story of a girl who grew up alone on a deserted island), ask, "Have you ever had to stay alone for a long time? How did you feel?"
2. Teach the concept of area by having students measure two schoolrooms that are different sizes.

Give opportunities to classify and group objects and ideas on increasingly complex levels.

Examples

1. Give students slips of paper with individual sentences written on each paper, and ask the students to group the sentences into paragraphs.
2. Compare the systems of the human body to other kinds of systems: the brain to a computer, the heart to a pump. Break down stories into components, from the broad to the specific: author, story, characters, plot, theme, place, time.

Present problems that require logical, analytical thinking.

Examples

1. Discuss open-ended questions that stimulate thinking: "Are the brain and the mind the same thing?" "How should the city deal with stray animals?" "What is the largest number?"
2. Use sports photos or pictures of crisis situations (Red Cross helping in disasters, victims of poverty or war, senior citizens who need assistance) to stimulate problem-solving discussions.

In any grade you teach, knowledge of concrete-operational thinking will be helpful (see *Guidelines: Teaching the Concrete-Operational Child*). In the early grades, the students are moving toward this logical system of thought. In the middle grades, it is in full flower, ready to be applied and extended by your teaching. Students in high school and even adults still commonly use concrete-operational thinking, especially in areas that are new or unfamiliar.

HIGH SCHOOL AND COLLEGE: FORMAL OPERATIONS. With the abilities to handle operations such as conservation, classification, and seriation, the student at the concrete-operational stage has finally developed a complete and very logical system of thinking, but this thinking is still tied to physical reality and the way things actually are. The child is not yet able to reason about hypothetical, abstract problems that involve the coordination of many factors at once. Such coordination is part of Piaget's final stage of cognitive development, **formal operations**. At this stage the focus of thinking can shift from *what is* to *what might be*. Situations do not have to be experienced to be imagined.

You met Jamal at the beginning of this chapter. Even though he is a bright elementary school student, he could not answer the question, "How would life be different if

Formal operations Mental tasks involving abstract thinking and coordination of a number of variables.

people did not have to sleep?” because he insisted, “People HAVE TO SLEEP!” In contrast, the adolescent who has mastered formal operations can consider contrary-to-fact questions. In answering, the adolescent demonstrates the hallmark of formal operations—**hypothetico-deductive reasoning**. The formal-operational thinker can consider a hypothetical situation (people do not sleep) and reason *deductively* (from the general assumption to specific implications, such as longer workdays, more money spent on energy and lighting, smaller houses without bedrooms, or new entertainment industries). Formal operations also include *inductive* reasoning, or using specific observations to identify general principles. For example, the economist observes many specific changes in the stock market and attempts to identify general principles about economic cycles from this information.

Using formal operations is a new way of reasoning that involves “thinking about thinking” or “mental operations on mental operations” (Inhelder & Piaget, 1958). For example, the child using concrete operations can categorize animals by their physical characteristics or by their habitats, but a child using formal operations can perform “second-order” operations on these category operations to *infer relationships between* habitat and physical characteristics—such as understanding that the physical characteristic of thick fur on animals is related to their arctic habitats (Kuhn & Franklin, 2006). Abstract formal-operational thinking is necessary for success in many advanced high school and college courses. Most math is concerned with hypothetical situations, assumptions, and givens: “Let $x = 10$,” or “Assume $x^2 + y^2 = z^2$,” or “Given two sides and an adjacent angle. . . .” Work in social studies and literature requires abstract thinking, too: “What did Wilson mean when he called World War I the ‘war to end all wars’?” “What are some metaphors for hope and despair in Shakespeare’s sonnets?” “What symbols of old age does T. S. Eliot use in *The Waste Land*?” “How do animals symbolize human character traits in Aesop’s fables?”

STOP & THINK You are packing for a long trip, but want to pack light. How many different three-piece outfits (slacks, shirt, jacket) will you have if you include three shirts, three pairs of slacks, and three jackets (assuming of course that they all go together in fashion perfection)? Time yourself to see how long it takes to arrive at the answer. •

The organized, scientific thinking of formal operations requires that students systematically generate all possibilities for a given situation. If asked the *Stop & Think* question above, the child using formal operations can identify all 27 possible combinations. (Did you get it right?) A concrete-operational thinker might name just a few combinations, using each piece of clothing only once.

Another characteristic of this stage is **adolescent egocentrism**. Unlike egocentric young children, adolescents do not deny that other people may have different perceptions and beliefs; the adolescents just become very focused on their own ideas and thoughts. This leads to what Elkind (1981) calls the sense of an *imaginary audience*—the feeling that everyone is watching: “Everyone noticed that I wore this shirt twice this week.” “The whole class thought my answer was dumb!” You can see that social blunders or imperfections in appearance can be devastating if “everybody is watching.” Luckily, this feeling of being “on stage” seems to peak in early adolescence by age 14 or 15, although in unfamiliar situations we all may feel our mistakes are being broadcast for everyone to see.

The ability to think hypothetically, consider alternatives, identify all possible combinations, and analyze their own thinking has some interesting consequences for adolescents. Because they can think about worlds that do not exist, they often become interested in science fiction. Because they can reason from general principles to specific actions, they often are critical of people whose actions seem to contradict their principles. Adolescents can deduce the set of “best” possibilities and imagine ideal worlds (or ideal parents and teachers, for that matter). This explains why many students at this age develop interests in utopias, political causes, and social issues. Adolescents also can imagine many possible futures for themselves and may try to decide which is best. Feelings about any of these ideals may be strong.

Connect and Extend to PRAXIS II®

Reasoning (II, A1)

Be able to distinguish between inductive and deductive reasoning. Explain the role that each plays in the learning of concepts.

Hypothetico-deductive reasoning

A formal-operations problem-solving strategy in which an individual begins by identifying all the factors that might affect a problem and then deduces and systematically evaluates specific solutions.

Adolescent egocentrism

Assumption that everyone else shares one’s thoughts, feelings, and concerns.

DO WE ALL REACH THE FOURTH STAGE? Most psychologists agree that there is a level of thinking more sophisticated than concrete operations, but do we all reach that level? The first three stages of Piaget's theory are forced on most people by physical realities. Objects really are permanent. The amount of water doesn't change when it is poured into another glass. Formal operations, however, are not so closely tied to the physical environment. Being able to use formal operations may be the result of practice in solving hypothetical problems and using formal scientific reasoning—abilities that are valued and taught in literate cultures in high school and college. But even in these cultures, not all high school students or adults can perform Piaget's formal-operational tasks (Shayer, 2003). Formal thinking might develop only in areas where adolescents and adults have experience or interest or take advanced classes (Lehman & Nisbett, 1990; Piaget, 1974). So expect many students in your middle school or high school classes to have trouble thinking hypothetically, especially when they are learning something new. Students sometimes find shortcuts for dealing with problems that are beyond their grasp; they may memorize formulas or lists of steps. These systems may be helpful for passing tests, but real understanding will take place only if students can go beyond this superficial use of memorization. The *Guidelines: Helping Students to Use Formal Operations* will help you support the development of formal operations in your students.

Some Limitations of Piaget's Theory

Although most psychologists agree with Piaget's insightful descriptions of *how* children think, many disagree with his explanations of *why* thinking develops as it does.

THE TROUBLE WITH STAGES. Some psychologists have questioned the existence of four separate stages of thinking, even though they agree that children do go through the changes that Piaget described (Mascolo & Fischer, 2005; P. H. Miller, 2016). One problem with the stage model is the lack of consistency in children's thinking. For example, children can conserve number (the number of blocks does not change when they are rearranged) a

GUIDELINES

Helping Students to Use Formal Operations

Continue to use concrete-operational teaching strategies and materials.

Examples

1. Use visual aids such as charts and illustrations as well as somewhat more sophisticated graphs and diagrams, especially when the material is new.
2. Compare the experiences of characters in stories to students' experiences.

Give students the opportunity to explore many hypothetical questions.

Examples

1. Have students write position papers, then exchange these papers with the opposing side and debate topical social issues such as the environment, the economy, and national health insurance.
2. Ask students to write about their personal vision of a utopia; write a description of a universe that has no sex differences; write a description of Earth after humans are extinct.

Give students opportunities to solve problems and reason scientifically.

Examples

1. Set up group discussions in which students design experiments to answer questions.
2. Ask students to justify two different positions on animal rights, with logical arguments for each position.

Whenever possible, teach broad concepts, not just facts, using materials and ideas relevant to the students' lives (Delpit, 1995).

Examples

1. When discussing the Civil War, consider racism or other issues that have divided the United States since then.
2. When teaching about poetry, let students find lyrics from popular songs that illustrate poetic devices, and talk about how these devices do or don't work well to communicate the meanings and feelings the songwriters intended.

year or two before they can conserve weight (the weight of a ball of clay does not change when you flatten it). Why can't they use conservation consistently in every situation?

Another problem with the idea of separate stages is that the processes may be more continuous than they seem. Changes may seem like discontinuous, qualitative leaps when we look across longer time periods. The 3-year-old persistently searching for a lost toy seems qualitatively different from the infant who doesn't miss a toy or search when the toy rolls under a sofa. But if we watched a developing child very closely and observed moment-to-moment or hour-to-hour changes, we might see that indeed there are gradual, continuous changes. Rather than appearing all at once, the knowledge that a hidden toy still exists may be a product of the older child's more fully developed memory: He knows that the toy is under the sofa because he remembers seeing it roll there, whereas the infant can't hold on to that memory. The longer you require children to wait before searching—the longer you make them remember the object—the older they have to be to succeed (Siegler & Alibali, 2005).

Change can be both continuous and discontinuous, as described by a branch of mathematics called *catastrophe theory*. Changes that appear suddenly, like the collapse of a bridge, are preceded by many slowly developing changes such as gradual, continuous corrosion of the metal structures. Similarly, gradually developing changes in children can lead to large changes in abilities that seem abrupt (Bjorklund, 2012; Dawson-Tunik, Fischer, & Stein, 2004; Siegler & Alibali, 2005). In fairness, we should note that in his later work, even Piaget put less emphasis on *stages* of cognitive development and gave more attention to how thinking *changes* through equilibration (P. H. Miller, 2016).

UNDERESTIMATING CHILDREN'S ABILITIES. It now appears that Piaget underestimated the cognitive abilities of children, particularly younger ones. The problems he gave young children may have been too difficult and the directions too confusing. His subjects may have understood more than they could demonstrate when solving these problems. For example, work by Gelman and her colleagues (Gelman, 2000; Gelman & Cordes, 2001) shows that preschool children know much more about the concept of number than Piaget thought, even if they sometimes make mistakes or get confused. As long as preschoolers work with only 3 or 4 objects at a time, they can tell that the number remains the same, even if the objects are spread far apart or clumped close together. Mirjam Ebersbach (2009) demonstrated that most of the German kindergartners in her study considered all three dimensions—width, height, and length—when they estimated the volume of a wooden block (actually, how many small cubes it would take to make bigger blocks of different sizes). In other words, we may be born with a greater store of cognitive tools than Piaget suggested. Some basic understandings or core knowledge, such as the permanence of objects or the sense of number, may be part of our evolutionary equipment, ready for use in our cognitive development (Berk & Meyers, 2016; Woodward & Needham, 2009).

Finally, Piaget argued that the development of cognitive operations such as conservation or abstract thinking cannot be accelerated. He believed that children had to be developmentally ready to learn. Quite a bit of research, however, has shown that with effective instruction, children can learn to perform cognitive operations such as conservation. They do not have to naturally discover these ways of thinking on their own. Knowledge and experience in a situation affect the kind of thinking that students can do (Brainerd, 2003).

COGNITIVE DEVELOPMENT AND CULTURE. One final criticism of Piaget's theory is that it overlooks the important effects of the child's cultural and social group. Research across different cultures has generally confirmed that although Piaget was accurate about the sequence of the stages in children's thinking, the age ranges for the stages vary. Western children typically move to the next stage about 2 to 3 years earlier than children in non-Western societies. But careful research has shown that these differences across cultures depend on the subject or domain tested and whether the culture values and teaches knowledge in that domain. For example, children in Brazil who sell candy in the streets instead of attending school appear to fail a certain kind of Piagetian task—class inclusion

(Are there more daisies, more tulips, or more flowers in the picture?). But when the tasks are phrased within concepts they understand—selling candy—then these children perform better than Brazilian children the same age who attend school (Saxe, 1999). When a culture or context emphasizes a cognitive ability, children growing up in that culture tend to acquire that ability sooner. In a study that compared Chinese first-, third-, and fifth-grade students to American students in the same grades, the Chinese students mastered a Piagetian task that involved distance, time, and speed relationships about 2 years ahead of American students, most likely because the Chinese education system puts more emphasis on math and science in the early grades (Zhou, Peverly, Beohm, & Chongde, 2001).

Even concrete operations such as classification may develop differently in different cultures. For example, when individuals from the Kpelle people of Africa were asked to sort 20 objects, they created groups that made sense to them—a hoe with a potato, a knife with an orange. The experimenter could not get the Kpelle to change their categories; they said this way of sorting is how a wise man would do it. Finally, the experimenter asked in desperation, “Well, how would a fool do it?” The subjects promptly created the four neat classification piles the experimenter had expected—food, tools, and so on (Rogoff & Morelli, 1989).

Information Processing, Neo-Piagetian, and Neuroscience Views of Cognitive Development

As you will see in Chapter 8, there are explanations for why children have trouble with conservation and other Piagetian tasks. These explanations focus on the development of information processing skills, such as attention, memory capacity, and learning strategies. As children mature and their brains develop, they are better able to focus their attention, process information more quickly, hold more information in memory, and use thinking strategies more easily and flexibly (Berk & Meyers, 2016; Siegler, 2000, 2004). One critical development is improvement in executive functioning. **Executive functioning** involves all those processes that we use to organize, coordinate, and perform goal-directed, intentional actions. Executive functioning skills include focusing attention, inhibiting impulsive responses, making and changing plans, and using memory to hold and manipulate information (Best & Miller, 2010; Raj & Bell, 2010). As children develop more sophisticated and effective executive functioning skills, they are active in advancing their own development; they are constructing, organizing, and improving their own knowledge and strategies (Siegler & Alibali, 2005). For example, one classic Piagetian task is to show children 10 daisies and 2 roses, then ask if there are more daisies or more flowers. Young children see more daisies and jump to the answer, “daisies.” As they mature, children are better at resisting (inhibiting) that first response based on appearances and can answer based on the fact that both daisies and roses are flowers. But even adults have to take a fraction of a second to resist the obvious, so inhibiting impulsive responses is important for developing complex knowledge throughout life (Borst, Poirrel, Pineau, Cassotti, & Houdé, 2013).

Some developmental psychologists have formulated **neo-Piagetian theories** that retain Piaget’s insights about children’s construction of knowledge and the general trends in children’s thinking but add findings from information processing theories about the role of attention, memory, and strategies (Croker, 2012). Perhaps the best-known neo-Piagetian theory was developed by Robbie Case (1992, 1998). He devised an explanation of cognitive development suggesting that children develop in stages within specific domains such as numerical concepts, spatial concepts, social tasks, storytelling, reasoning about physical objects, and motor development. As children practice using the schemes in a particular domain (e.g., using counting schemes in the number concept area), accomplishing the schemes requires less attention and working memory space. The schemes become more automatic because the child does not have to “think so hard.” This frees up mental resources and memory to do more, so the child can combine simple schemes into more complex ones and invent new schemes when needed (assimilation and accommodation in action).

Kurt Fischer (2009) connected cognitive development in different domains to research on the brain. Even though children may follow different pathways as they

Executive functioning All those processes that we use to organize, coordinate, and perform goal-directed, intentional actions, including focusing attention, inhibiting impulsive responses, making and changing plans, and using memory to hold and manipulate information.

Neo-Piagetian theories More recent theories that integrate findings about attention, memory, and strategy use with Piaget’s insights about children’s thinking and the construction of knowledge.

master skills in speaking, reading, and mathematics, their growth patterns show a similar series of spurts and they go through predictable levels of development. When learning a new skill, children move through three tiers—from *actions* to *representations* to *abstractions*. Within each tier, the pattern is moving from accomplishing a single action to mapping or coordinating two actions together, such as coordinating addition and multiplication in math, to creating whole systems of understanding. At the level of abstractions, children finally move to constructing explanatory principles. This may remind you of sensorimotor, concrete operations, and formal operations in Piaget's theory. For each skill level, the brain reorganizes itself, too. In this process, skills develop sooner at each level with the chance to practice and quality support. Support and practice are keys in another explanation of cognitive development we will discuss next—Vygotsky's theory.

MyLab Education Self-Check 2.3

VYGOTSKY'S SOCIOCULTURAL PERSPECTIVE

Psychologists today recognize that culture shapes cognitive development by determining what and how the child will learn about the world—the content and processes of thinking. For example, cultures that prize cooperation and sharing teach these abilities early, whereas cultures that encourage competition nurture competitive skills in their children. The stages observed by Piaget are not necessarily “natural” for all children because to some extent they reflect the expectations and activities of Western cultures, as the Kpelle people described earlier have taught us (Kozulin, 2003; Kozulin et al., 2003; Rogoff, 2003).

A major spokesperson for this **sociocultural theory** (also called *sociohistoric*) was a Russian Jewish psychologist who was born the same year as Piaget—1896. Lev Semenovich Vygotsky was only 37 when he died of tuberculosis, but during his brief life he produced over 100 books and articles. Some of the translations are now available (e.g., Vygotsky, 1978, 1986, 1987a, 1987b, 1987c, 1993, 1997). Vygotsky began studying learning and development to improve his own teaching. He went on to write about language and thought, the psychology of art, learning and development, and educating students with special needs. His work was banned in Russia for many years because he referenced Western psychologists. But in the past 50 plus years, with the rediscovery of his writings, Vygotsky's ideas have become major influences in psychology and education and have provided alternatives to many of Piaget's theories (Gredler, 2009a, 2009b, 2012; Kozulin, 2003; Kozulin et al., 2003; Moll, 2014; Van Der Veer, 2007; Wink & Putney, 2002).

Vygotsky believed that human activities take place in cultural settings and that they cannot be understood apart from these settings. One of his key ideas was that our specific mental structures and processes can be traced to our interactions with others. These social interactions are more than simple influences on cognitive development—they actually create our cognitive structures and thinking processes (Palincsar, 1998). In fact, “Vygotsky conceptualized development as the transformation of socially shared activities into internalized processes” (John-Steiner & Mahn, 1996, p. 192). We will examine three themes in Vygotsky's writings that explain how social processes form learning and thinking: the social sources of individual thinking; the role of cultural tools in learning and development, especially the tool of language; and the zone of proximal development (Driscoll, 2005; Gredler, 2012; P. H. Miller, 2016).

The Social Sources of Individual Thinking

Vygotsky assumed that

Every function in a child's cultural development appears twice: first, on the social level and later on the individual level; first between people (interpsychological) and then inside the child (intrapsychological). This applies equally to voluntary attention, to logical memory, and to the formation of concepts. All the higher functions originate as actual relations between human individuals. (Vygotsky, 1978, p. 57)

Sociocultural theory

Emphasizes role in development of cooperative dialogues between children and more knowledgeable members of society. Children learn the culture of their community (ways of thinking and behaving) through these interactions.

In other words, higher mental processes, such as directing your own attention and thinking through problems, first are *co-constructed* during shared activities between the child and another person. Then these **co-constructed processes** are internalized by the child and become part of that child's cognitive development (Gredler, 2009a, 2009b; Mercer, 2013). For example, children first use language in activities with others to try to regulate their behavior ("No nap!" or "I wanna cookie."). Later, however, the child can regulate her own behavior using private speech ("careful—don't spill"), as you will see in a later section. So, for Vygotsky, social interaction was more than influence; it was the origin of higher mental processes such as problem solving. Consider this example:

A six-year-old has lost a toy and asks her father for help. The father asks her where she last saw the toy; the child says "I can't remember." He asks a series of questions—did you have it in your room? Outside? Next door? To each question, the child answers, "no." When he says "in the car?" she says "I think so" and goes to retrieve the toy. (Tharp & Gallimore, 1988, p. 14)

Who remembered? The answer is really neither the father nor the daughter, but the two together. The remembering and problem solving were co-constructed—between people—in the interaction. But the child (and the father) may have internalized strategies to use the next time something is lost. At some point, the child will be able to function independently to solve this kind of problem. So, like the strategy for finding the toy, higher functions appear first between a child and a "teacher" before they exist within the individual child (Kozulin, 2003; Kozulin et al., 2003; P. H. Miller, 2016).

Here is another example of the social sources of individual thinking. Richard Anderson and his colleagues (2001) studied how fourth graders in small-group classroom discussions *appropriate* (take for themselves and use) argument stratagems that occur in the discussions. An *argument stratagem* is a particular form such as "I think [POSITION] because [REASON]," where the student fills in the position and the reason. For example, a student might say, "I think that the wolves should be left alone because they are not hurting anyone." Another strategy form is "If [ACTION], then [BAD CONSEQUENCE]," as in "If they don't trap the wolves, then the wolves will eat the cows." Other forms manage participation, for example, "What do you think [NAME]?" or "Let [NAME] talk."

Anderson's research identified 13 forms of talk and argument that helped to manage the discussion, get everyone to participate, present and defend positions, and handle confusion. The use of these different forms of talking and thinking *snowballed*: Once a useful argument was employed by one student, it spread to other students, and the argument stratagem form appeared more and more in the discussions. Open discussions—students asking and answering each other's questions—were better than teacher-dominated discussion for the development of these argument forms. Over time, these ways of presenting, attacking, and defending positions could be internalized as mental reasoning and decision making for the individual students.

Both Piaget and Vygotsky emphasized the importance of social interactions in cognitive development, but Piaget saw a different role for interaction. He believed that interaction encouraged development by creating disequilibrium—that is, cognitive conflict motivated change. Thus, Piaget believed that the most helpful interactions were those between peers, because peers are on an equal basis and can challenge each other's thinking. Vygotsky, on the other hand, suggested that children's cognitive development is fostered by interactions with people who are more capable or advanced in their thinking—people such as parents and teachers. Of course, students can learn from both adults and peers, and today, computers can play a role in supporting communication across distances or in different languages.

Co-constructed process

A social process in which people interact and negotiate (usually verbally) to create an understanding or to solve a problem. The final product is shaped by all participants.

Cultural tools The real tools (computers, scales, etc.) and symbol systems (numbers, language, graphs) that allow people in a society to communicate, think, solve problems, and create knowledge.

Cultural Tools and Cognitive Development

Vygotsky believed that **cultural tools**, including technical tools (e.g., printing presses, plows, rulers, abacuses, graph paper—today, we would add mobile devices, computers, the Internet, real-time translators for mobile devices and chats, search engines, digital organizers and calendars, assistive technologies for students with learning

challenges, etc.) and psychological tools (signs and symbol systems such as numbers and mathematical systems, Braille and sign language, maps, works of art, codes, and language) play very important roles in cognitive development. For example, as long as the culture provides only Roman numerals for representing quantity, certain ways of thinking mathematically—from long division to calculus—are difficult or impossible. But if a number system has a zero, fractions, positive and negative values, and an infinite quantity of numbers, then much more is possible. The number system is a psychological tool that supports learning and cognitive development—it changes the thinking process. This symbol system is passed from adult to child and from child to child through formal and informal interactions and teachings.

TECHNICAL TOOLS IN A DIGITAL AGE. The use of technical tools such as calculators and spell checkers has been somewhat controversial in education. Technology is increasingly “checking up” on us. I rely on the spell checker in my word processing program to protect me from embarrassment. But I also read student papers with spelling replacements that must have come from decisions made by the word processing program—without a “sense check” by the writer. Is student learning harmed or helped by these technology supports? Just because students learned mathematics in the past with paper-and-pencil procedures does not mean that this is the best way to learn. In fact, the research on calculators has found that rather than eroding basic skills, calculator use has positive effects on students’ problem-solving skills and attitudes toward math (Ellington, 2003, 2013; Waits & Demana, 2000). There is a catch, however. On simple math problems it probably is better to attempt recalling or calculating the answer first before turning to a calculator. Math fact learning and fluency in arithmetic are supported when students self-generate answers before resorting to calculators (Pyke & LeFevre, 2011).

PSYCHOLOGICAL TOOLS. Vygotsky believed that all higher-order mental processes such as reasoning and problem solving are *mediated* by (accomplished through and with the help of) psychological tools. These tools allow children to transform their thinking by enabling them to gain greater and greater mastery of their own cognitive processes; they advance their own development as they use the tools. Vygotsky believed the essence of cognitive development is mastering the use of psychological tools such as language to accomplish the kind of advanced thinking and problem solving that could not be accomplished without those tools (Gredler, 2012; Karpov & Haywood, 1998). The process is something like this: As children engage in activities with adults or more capable peers, they exchange ideas and ways of thinking about or representing concepts—drawing maps, for example, as a way to represent spaces and places. Children internalize these co-created ideas. Children’s knowledge, ideas, attitudes, and values develop through *appropriating* or “taking for themselves” the ways of acting and thinking provided by both their culture and other members of their group (Wertsch, 2007).

In this exchange of signs and symbols and explanations, children begin to develop a “cultural tool kit” to make sense of and learn about their world (Wertsch, 1991). The kit is filled with technical tools such as graphing calculators or rulers directed toward the external world and psychological tools for acting mentally such as concepts, problem-solving strategies, and (as we saw earlier) argument strategems. Children do not just receive the tools, however. They transform the tools as they construct their own representations, symbols, patterns, and understandings. These understandings gradually change as the children continue to engage in social activities and try to make sense of their world (John-Steiner & Mahn, 1996; Wertsch, 1991). In Vygotsky’s theory, language is the most important symbol system in the tool kit, and it is the one that helps to fill the kit with other tools.

The Role of Language and Private Speech

Language is critical for cognitive development because it provides a way to express ideas and ask questions, the categories and concepts for thinking, and the links between the past and the future. Language frees us from the immediate situation so we can think

about what was and what might be (Driscoll, 2005; Mercer, 2013). Vygotsky thought that:

the specifically human capacity for language enables children to provide for auxiliary tools in the solution of difficult tasks, to overcome impulsive action, to plan a solution to a problem prior to its execution, and to master their own behavior. (Vygotsky, 1978, p. 28)

Vygotsky placed more emphasis than Piaget on the role of learning and language in cognitive development. And Vygotsky believed that language in the form of private speech (talking to yourself) guides cognitive development.

PRIVATE SPEECH: VYGOTSKY'S AND PIAGET'S VIEWS COMPARED. If you have spent much time around young children, you know that they often talk to themselves as they play. This can happen when the child is alone or, even more often, in a group of children—each child talks enthusiastically, without any real interaction or conversation. Piaget called this the **collective monologue**, and he labeled all of the children's self-directed talk “egocentric speech.” He assumed that this egocentric speech is another indication that young children can't see the world through the eyes of others, so they chat away without taking into account the needs or interests of their listeners. As they mature, and especially as they have disagreements with peers, Piaget believed, children develop *socialized speech*. They learn to listen and exchange (or argue) ideas.

Vygotsky had very different ideas about young children's **private speech**. He suggested that rather than being a sign of cognitive immaturity, these mutterings play an important role in cognitive development because they move children in stages toward *self-regulation*: the ability to plan, monitor, and guide your own thinking and problem solving. First the child's behavior is regulated by others using language and other signs such as gestures. For example, the parent says, “No!” when the child reaches toward a candle flame. Next, the child learns to regulate the behavior of others using the same language tools. The child says “No!” to another child who is trying to take away a toy, often even imitating the parent's voice tone. The child also begins to use private speech to regulate her own behavior, saying “no” quietly to herself as she is tempted to touch the flame. Finally, the child learns to regulate her own behavior by using silent inner speech (Karpov & Haywood, 1998).

For example, in any preschool room you might hear 4- or 5-year-olds saying, “No, it won't fit. Try it here. Turn. Turn. Maybe this one!” while they do puzzles. Around the age of 7, children's self-directed speech goes underground, changing from spoken to whispered speech and then to silent lip movements. Finally, the children just “think” the guiding words. The use of private speech peaks at around age 9 and then decreases, although one study found that some students from ages 11 to 17 still spontaneously muttered to themselves during problem solving (McCafferty, 2004; Winsler, Carlton, & Barry, 2000; Winsler & Naglieri, 2003). Vygotsky called this inner speech “an internal plane of verbal thinking” (Vygotsky, 1934/1987c, p. 279)—a critical accomplishment on the road to higher-order thinking.

This series of steps from spoken words to silent inner speech is another example of how higher mental functions first appear between people as they communicate and regulate each other's behavior, and then emerge again within the individual as cognitive processes. Through this fundamental process, the child is using language to accomplish important cognitive activities such as directing attention, solving problems, planning, forming concepts, and gaining self-control. Research supports Vygotsky's ideas (Berk & Spuhl, 1995; Emerson & Miyake, 2003). Children and adults tend to use more private speech when they are confused, having difficulties, or making mistakes (R. M. Duncan & Cheyne, 1999). Have you ever thought to yourself something like, “Let's see, the first step is” or “Where did I use my glasses last?” or “If I read to the end of this page, then I can . . .”? You were using inner speech to remind, cue, encourage, or guide yourself.

This internal verbal thinking is not stable until about age 12, so children in elementary school may need to continue talking through problems and explaining their

Collective monologue Form of speech in which children in a group talk but do not really interact or communicate.

Private speech Children's self-talk, which guides their thinking and action. Eventually, these verbalizations are internalized as silent inner speech.

reasoning in order to develop their abilities to control their thinking (Gredler, 2012). Because private speech helps students regulate their thinking, it makes sense to allow, and even encourage, students to use private speech in school. Teachers' insisting on total silence when young students are working on difficult problems may make the work even harder for them. Take note when muttering increases in your class—this could be a sign that students need help.

Table 2.4 contrasts Piaget's and Vygotsky's theories of private speech. We should note that Piaget accepted many of Vygotsky's arguments and came to agree that language could be used in both egocentric and problem-solving ways (Piaget, 1962).

The Zone of Proximal Development

According to Vygotsky, at any given point in development, a child is on the verge of solving certain problems—"processes that have not matured at the time but are in a period of maturation" (Vygotsky, 1930–1931/1998, p. 201). The child just needs some structure, demonstrations, clues, reminders, help with remembering details or steps, encouragement to keep trying, and so on. Some problems, of course, are beyond the child's capabilities, even if every step is explained clearly. The **zone of proximal development (ZPD)** is the area between the child's current performance (the problems the child can solve independently without any support) and the level of performance that the child could achieve with adult guidance or by working with "a more fully developed child" (p. 202). It is a dynamic and changing space as student and teacher interact and understandings are exchanged. This is the area where instruction can succeed. Kathleen Berger (2015; 2016) called this area the "magic middle"—somewhere between what the student already knows and what the student isn't ready to understand or learn yet.

PRIVATE SPEECH AND THE ZONE. We can see how Vygotsky's beliefs about the role of private speech in cognitive development fit with the notion of the ZPD. Often, an adult uses verbal prompts and structuring to help a child solve a problem or accomplish a task. We will see later that this type of support has been called *scaffolding*. This support can be gradually reduced as the child takes over the guidance, perhaps first by giving the prompts as private speech and finally as inner speech. As an example, think of the young girl described earlier who had lost her toy. Let's move forward several years

MyLab Education Video Example 2.3

In this video, one teacher guides young children in putting together puzzles and another guides a boy to create a pattern by organizing toy trucks based on color. Is the process of organizing toys in a pattern based on color a skill that is in the boy's zone of proximal development, or is it still too advanced for a child at his developmental level?

Zone of proximal development (ZPD) Phase at which a child can master a task if given appropriate help and support.

TABLE 2.4 • Differences Between Piaget's and Vygotsky's Theories of Egocentric, or Private, Speech

	PIAGET	VYGOTSKY
Meaning and Purpose	Represents an inability to take the perspective of another and engage in reciprocal communication.	Represents externalized thought; its function is to communicate with the self for the purpose of self-guidance and self-direction.
Course of Development	Declines with age.	Increases at younger ages and then gradually loses its audible quality to become internal verbal thought.
Relationship to Social Speech	Negative; the least socially and cognitively mature children use more egocentric speech.	Positive; private speech develops out of social interaction with others.
Relationship to Environmental Contexts	No relationship	Increases with task difficulty. Private speech serves a helpful self-guiding function in situations where more cognitive effort is needed to reach a solution.

in her life and listen to her *thoughts* as an older student when she realizes that a school-book is missing. They might sound something like this:

“Where’s my math book? Used it in class. Thought I put it in my book bag after class. Dropped my bag on the bus. That dope Larry kicked my stuff, so maybe. . . .”

The girl can now systematically search for ideas about the lost book without help from anyone.

THE ROLE OF LEARNING AND DEVELOPMENT. Piaget defined *development* as the active construction of knowledge and *learning* as the passive formation of associations (Siegler, 2000). He was interested in knowledge construction and believed that cognitive development has to come before learning—the child had to be cognitively “ready” to learn. Students can memorize, for example, that Geneva is in Switzerland, but still insist that they cannot be Genevan and Swiss at the same time. True understanding will take place only when the child has developed the operation of *class inclusion*—that one category can be included within another. But as we saw earlier, research has not supported Piaget’s position on the need for cognitive development to precede learning (Brainerd, 2003).

In contrast, Vygotsky believed that learning is an active process that does not have to wait for readiness. He saw learning as a tool in development; learning pulls development up to higher levels, and social interaction is a key in learning. In other words, what develops next is what is affected by learning (Bodrova & Leong, 2012; Gredler, 2012; Wink & Putney, 2002). This means that other people, including teachers, play a significant role in cognitive development. It does not mean that Vygotsky believed memorization is learning. When teachers try to directly communicate their understanding, the result can be a “meaningless acquisition of words” and “mere verbalization” (Vygotsky 1934/1987b, p. 356) that actually hides an understanding vacuum (Gredler, 2012). In Vygotsky’s words, the teacher “explains, informs, inquires, corrects, and forces the child to explain” (p. 216).

Limitations of Vygotsky’s Theory

Vygotsky’s theory added important considerations by highlighting the role of culture and social processes in cognitive development, but he may have gone too far. As you have seen in this chapter, we may be born with a greater store of cognitive tools than either Piaget or Vygotsky suggested. Some basic understandings, such as the idea that adding increases quantity, may be part of our biological predispositions, ready for use to guide our cognitive development. Young children appear to figure out much about the world before they have the chance to learn from either their culture or their teachers (Schunk, 2016; Woodward & Needham, 2009). The major limitation of Vygotsky’s theory, however, is that it consists mostly of general ideas; Vygotsky died before he could expand and elaborate on his ideas and pursue his research. His students continued to investigate his ideas, but much of that work was suppressed by Stalin’s regime until the 1950s and 1960s (Gredler, 2005, 2009b; Kozulin, 2003; Kozulin et al., 2003). A final limitation might be that Vygotsky did not have time to detail the applications of his theories for teaching, even though he was very interested in instruction. As a result, most of the applications described today have been created by others—and we don’t even know if Vygotsky would agree with them. It is clear that some of his concepts, like ZPD, have been misrepresented at times (Gredler, 2012).

MyLab Education [Self-Check 2.4](#)

IMPLICATIONS OF PIAGET’S AND VYGOTSKY’S THEORIES FOR TEACHERS

Piaget did not make specific educational recommendations, and Vygotsky did not have enough time to develop a complete set of applications. But we can glean some guidance from both men.

Piaget: What Can We Learn?

Piaget was more interested in understanding children's thinking than in guiding teachers. He did express some general ideas about educational philosophy, however. He believed that the main goal of education should be to help children learn how to learn, and that education should "form not furnish" the minds of students (Piaget, 1969, p. 70). Piaget has taught us that we can learn a great deal about how children think by listening carefully and by paying close attention to their ways of solving problems. If we understand children's thinking, we will be better able to match teaching methods to children's current knowledge and abilities; in other words, we will be better able to differentiate instruction.

Even though Piaget did not design programs of education based on his ideas, his influence on current educational practice is huge (Hindi & Perry, 2007). For example, the National Association for the Education of Young Children has guidelines for developmentally appropriate practice (DAP) that incorporate Piaget's findings (Bredekamp, 2017; Bredekamp & Copple, 1997).

UNDERSTANDING AND BUILDING ON STUDENTS' THINKING. The students in any class will vary greatly in both their level of cognitive development and their academic knowledge. As a teacher, how can you determine whether students are having trouble because they lack the necessary thinking abilities or because they simply have not learned the basic facts? To do this, Case (1985) suggests you observe your students carefully as they try to solve the problems you have presented. What kind of logic do they use? Do they focus on only one aspect of the situation? Are they fooled by appearances? Do they suggest solutions systematically or by guessing and forgetting what they have already tried? Ask your students how they tried to solve the problem. Listen to their strategies. What kind of thinking is behind repeated mistakes or problems? Students are the best sources of information about their own thinking (Confrey, 1990).

An important implication of Piaget's theory for teaching is what J. Hunt years ago (1961) called, "the problem of the match." Students must be neither bored by work that is too simple nor left behind by teaching they cannot understand. According to Hunt, disequilibrium must be kept "just right" to encourage growth. Setting up situations that lead to unexpected results can help create an appropriate level of disequilibrium. When students experience some conflict between what they think should happen (a piece of wood should sink because it is big) and what actually happens (it floats!), they may rethink the situation, and new knowledge may develop.

Many materials and lessons can be understood at several levels and can be "just right" for a range of cognitive abilities. Classics such as *Alice in Wonderland*, myths, and fairy tales can be enjoyed at both concrete and symbolic levels. It is also possible for a group of students to be introduced to a topic together, and then work individually on follow-up activities matched to their learning needs. Using multilevel lessons is called *differentiated instruction* (Gipe, 2014; Tomlinson, 2005b). We will look at this approach more closely in Chapter 14.

ACTIVITY AND CONSTRUCTING KNOWLEDGE. Piaget's fundamental insight was that individuals construct their own understanding; learning is a constructive process. At every level of cognitive development, you will also want to see that students are actively engaged in the learning process. In Piaget's words:

Knowledge is not a copy of reality. To know an object, to know an event, is not simply to look at it and make a mental copy or image of it. To know an object is to act on it. To know is to modify, to transform the object, and to understand the process of this transformation, and as a consequence to understand the way the object is constructed. (Piaget, 1964, p. 8)

For example, research in teaching mathematics indicates that students from kindergarten to college remember basic facts better when they have learned using manipulative materials such as counting sticks, pattern blocks, fraction strips, or blocks, versus using abstract symbols only (Carbonneau, Marley, & Selig, 2013). Beware, however, of assuming that you can just give students manipulatives to work with and they will learn

Connect and Extend to PRAXIS II®

Implications of Piaget's Theory (I, A2)

The music, physical education, and art teachers in a rural, pre-K-to-8 school district work with students who characterize several of Piaget's stages. How should these three teachers adjust their teaching from level to level over the course of a week?

automatically. In one study, middle school students learned more science when teachers accompanied manipulatives with strong guidance about how to use them. Research in other subject areas has found similar results (Hushman & Marley, 2015; Marley & Carbonneau, 2014). This active experience, even at the earliest school levels, should not be limited to the physical manipulation of objects. It should also include mental manipulation of ideas that arise out of class projects or experiments (Gredler, 2005, 2012). For example, after a social studies lesson on different jobs, a primary-grade teacher might show students a picture of a woman and ask, “What could this person be?” After answers such as “teacher,” “doctor,” “secretary,” “lawyer,” “saleswoman,” and so on, the teacher could suggest, “How about a daughter?” Answers such as “sister,” “mother,” “aunt,” and “granddaughter” may follow. This should help the children switch dimensions in their classification and center on another aspect of the situation. Next, the teacher might suggest “American,” “jogger,” or “blonde.” With older children, hierarchical classification might be involved: It is a picture of a woman, who is a human being; a human being is a primate, which is a mammal, which is an animal, which is a life form.

All students need to interact with teachers and peers in order to test their thinking, to be challenged, to receive feedback, and to watch how others work out problems. Disequilibrium is often set in motion quite naturally when the teacher or another student suggests a new way of thinking about something. As a general rule, students should act on, manipulate, observe, and then talk and/or write about (to the teacher and each other) what they have experienced. Concrete experiences provide the raw materials for thinking. Communicating with others makes students use, test, and sometimes change their thinking strategies.

Connect and Extend to PRAXIS II®

Implications of Vygotsky's Theory (I, A2)

Make a list of scaffolding techniques that would be appropriate with different instructional levels and content areas. Think of scaffolding techniques that others have used when you learned things outside of school (e.g., sports, hobbies).

Scaffolding Support for learning and problem solving. The support could be clues, reminders, encouragement, breaking the problem down into steps, providing an example, or anything else that allows the student to grow in independence as a learner. Teachers and students make meaningful connections between what the teacher knows and what the students know and need in order to help the students learn more.

Vygotsky: What Can We Learn?

Like Piaget, Vygotsky believed that the main goal of education was the development of higher mental functions, not simply filling students' memories with facts. So Vygotsky probably would oppose educational curricula that are an inch deep and a mile wide or seem like “trivial pursuit.” As an example of this trivial pursuit curriculum, Margaret Gredler (2009a) described a set of materials for a 9-week science unit that had 61 glossary terms such as *aqueous solution*, *hydrogen bonding*, and *fractional crystallization*—many terms described with only one or two sentences.

There are at least three ways that higher mental functions can be developed through cultural tools and passed from one individual to another: *imitative* learning (one person tries to imitate the other), *instructed* learning (learners internalize the instructions of the teacher and use these instructions to self-regulate), and *collaborative* learning (a group of peers strives to understand each other and learning occurs in the process) (Tomasello, Kruger, & Ratner, 1993). Vygotsky was most concerned with the second type, *instructed* learning through direct teaching or by structuring experiences that encourage another's learning, but his theory supports learning through *imitation* or *collaboration* as well. Thus, Vygotsky's ideas are relevant for educators who teach directly, intentionally use modeling to teach, or create collaborative learning environments (Das, 1995; P. H. Miller, 2016; Wink & Putney, 2002). That pretty much includes all of us.

THE ROLE OF ADULTS AND PEERS. Vygotsky believed the child is not alone in the world “discovering” the cognitive operations of conservation or classification. This discovery is assisted or mediated by family members, teachers, peers, and even software tools (Puntambekar & Hubscher, 2005). Most of this guidance is communicated through language, at least in Western cultures. In some cultures, observing a skilled performance, not talking about it, guides the child's learning (Rogoff, 1990). Some people have called this adult assistance **scaffolding**, taken from Wood, Bruner, and Ross (1976). The idea is that children use the help for support while they build a firm understanding that will eventually allow them to solve the problems on their own. Actually, when Wood and his colleagues introduced the term *scaffolding*, they were talking about how teachers set up or structure learning environments, but Vygotsky's theory implies more dynamic exchanges that allow the teacher to support students in the parts of the task they cannot do alone—the interactions of assisted learning, as you will see next (Schunk, 2016).

TABLE 2.5 • Strategies to Provide Scaffolding and Assisted Learning

- Model the thought process for the students: Think out loud as you solve the problem or outline an essay, for example.
- Provide organizers or starters such as *who, what, why, how, what next?*
- Do part of the problem.
- Give hints and cues.
- Encourage students to set short-term goals and take small steps.
- Connect new learning to students' interests or prior learning.
- Use graphic organizers: timelines, charts, tables, categories, checklists, and graphs.
- Simplify the task, clarify the purpose, and give clear directions.
- Teach key vocabulary and provide examples.

ASSISTED LEARNING. Vygotsky's theory suggests that teachers need to do more than just arrange the environment so that students can discover on their own. Children cannot and should not be expected to reinvent or rediscover knowledge already available in their cultures. Rather, they should be guided and assisted in their learning (Karpov & Haywood, 1998).

Assisted learning, or guided participation, requires first learning from the student what is needed; then giving information, prompts, reminders, and encouragement at the right time and in the right amounts; and gradually allowing the students to do more and more on their own. Teachers can assist learning by adapting materials or problems to students' current levels; demonstrating skills or thought processes; walking students through the steps of a complicated problem; doing part of the problem (e.g., in algebra, the students set up the equation and the teacher does the calculations or vice versa); giving detailed feedback and allowing revisions; or asking questions that refocus students' attention (Rosenshine & Meister, 1992). Cognitive apprenticeships (Chapter 10) are examples. Look at Table 2.5 for examples of strategies that can be used in any lesson.

MyLab Education
Video Example 2.4

The children in this class are learning about earthworms. How does the teacher guide the students to encourage them to make their own discoveries?

An Example Curriculum: Tools of the Mind

Deborah Leong and Elena Bodrova (2012) worked for years to develop a curriculum for preschool through second-grade children based on Vygotsky's theory. In Russia, Dr. Bodrova had studied with students and colleagues of Vygotsky and wanted to bring his ideas to teachers. The result is the *Tools of the Mind* project that includes curriculum ideas for preschool, kindergarten, and special needs students (see toolsofthemind.org). One key idea taken from Vygotsky is that as children develop mental tools such as strategies for focusing attention, they cease being prisoners of their environment—having their attention “grabbed away” by any new sight or sound. They learn to control their attention. A second key idea is that play, particularly dramatic pretend play, is the most important activity supporting the development of young children. Through dramatic play children learn to focus attention, control impulses, follow rules, use symbols, regulate their own behaviors, and cooperate with others. So a key element of the *Tools of the Mind* curriculum for young children is play plans, created by the students themselves. Children draw a picture of how they plan to play that day, and then describe it to the teacher, who may make notes on the page and thus model literacy activities. Plans become more complex and detailed as children become better planners. Figure 2.5 on the next page shows Brandon's simple play plan at the beginning of age 3 and then another plan at the end of age 4. His later plan shows better fine motor control, more mature drawing, increased imagination, and greater use of language.

Reaching Every Student: Teaching in the “Magic Middle”

Both Piaget and Vygotsky probably would agree that students should be taught in the magic middle (Berger, 2015, 2016), or the place of the “match” (J. Hunt, 1961)—where they are neither bored nor frustrated. Students should be put in situations where they have to reach to understand but where support from other students, learning materials,

or the teacher is also available. Sometimes the best teacher is another student who has just figured out how to solve the problem, because this student is probably operating in the learner's ZPD. Having a student work with someone who is just a bit better at the activity would be a good idea because both students benefit in the exchange of explanations, elaborations, and questions. In addition, students should be encouraged to use language to organize their thinking and to talk about what they are trying to accomplish, as in Figure 2.5. Dialogue and discussion are important avenues to learning (Karpov & Bransford, 1995; Kozulin & Presseisen, 1995; Wink & Putney, 2002). The *Guidelines: Applying Vygotsky's Ideas in Teaching* give more ideas for applying Vygotsky's insights.

Cognitive Development: Lessons for Teachers

In spite of cross-cultural differences in cognitive development and the different theories of development, there are some convergences. Piaget, Vygotsky, and more recent researchers studying cognitive development and the brain probably would agree with the following big ideas:

1. Cognitive development requires both physical and social stimulation.
2. To develop thinking, children have to be mentally, physically, and linguistically active. They need to experiment with, talk about, describe, reflect on, write about, and solve problems. But they also benefit from teaching, guidance, questions, explanations, demonstrations, and challenges to their thinking.
3. Teaching students what they already know is boring. Trying to teach what the student isn't ready to learn is frustrating and ineffective.
4. Challenge with support will keep students engaged but not fearful.

GUIDELINES

Applying Vygotsky's Ideas in Teaching

Tailor scaffolding to the needs of students.

Examples

1. When students are beginning new tasks or topics, provide models, prompts, sentence starters, coaching, and feedback. As the students grow in competence, give less support and more opportunities for independent work.
2. Give students choices about the level of difficulty or degree of independence in projects; encourage them to challenge themselves but to seek help when they are really stuck.

Make sure students have access to powerful tools that support thinking.

Examples

1. Teach students to use learning and organizational strategies, research tools, language tools (wikis, dictionaries, or computer searches), spreadsheets, and word-processing programs.
2. Model the use of tools; show students how you use an appointment book or calendar app on your smartphone to make plans and manage time, for example.

Build on the students' cultural funds of knowledge

(N. Gonzalez, Moll, & Amanti, 2005; Moll et al., 1992).

Examples

1. Identify family knowledge by having students interview each other's families about their work and home knowledge (agriculture, economics, manufacturing, household management, medicine and illness, religion, child care, cooking, etc.).
2. Tie assignments to these funds of knowledge, and use community experts to evaluate assignments.

Capitalize on dialogue and group learning.

Examples

1. Experiment with peer tutoring; teach students how to ask good questions and give helpful explanations.
2. Experiment with cooperative learning strategies described in Chapter 10.

MyLab Education Self-Check 2.5

▼ SUMMARY

A Definition of Development (pp. 60–62)

What are the different kinds of development? Human development can be divided into physical development (changes in the body), personal development (changes in an individual's personality), social development (changes in the way an individual relates to others), and cognitive development (changes in thinking).

What are three questions about development and three general principles? For decades, psychologists and the public have debated whether development is shaped more by nature or nurture, whether change is a continuous process or involves qualitative differences or stages, and whether there are critical times for the development of certain abilities. We know today that these simple either/or distinctions cannot capture the complexities of human development where coactions and interactions are the rule. Theorists generally agree that people develop at different rates, that development is an orderly process, and that development takes place gradually.

The Brain and Cognitive Development (pp. 62–73)

What part of the brain is associated with higher mental functions? The cortex is a crumpled sheet of neurons that serves three major functions: receiving signals from sense organs (such as visual or auditory signals), controlling voluntary movement,

and forming connections. The part of the cortex that controls physical motor movement develops or matures first, then the areas that control complex senses such as vision and hearing, and last, the frontal lobe, which controls higher-order thinking processes.

What is lateralization, and why is it important? Lateralization is the specialization of the two sides, or hemispheres, of the brain. For most people, the left hemisphere is the major factor in language, and the right hemisphere is prominent in spatial and visual processing. Even though certain functions are associated with particular parts of the brain, the various parts and systems of the brain work together to learn and perform complex activities such as reading and constructing understanding.

What are some implications for teachers? Recent advances in both teaching methods and discoveries in the neurosciences provide exciting information about brain activity during learning and brain activity differences among people with varying abilities and challenges and from different cultures. These findings have some basic implications for teaching, but many of the strategies offered by “brain-based” advocates are simply good teaching. Perhaps we now know more about why these strategies work.

Piaget's Theory of Cognitive Development (pp. 73–85)

What are the main influences on cognitive development? Piaget's theory of cognitive development is based on the assumption that people try to make sense of the world and actively create knowledge through direct experiences with objects, people, and ideas. Maturation, activity, social transmission, and the need for equilibrium all influence cognitive development. In response to these influences, thinking processes and knowledge develop through changes in the organization of thought (the development of schemes) and through adaptation—including the complementary processes of assimilation (incorporating into existing schemes) and accommodation (changing existing schemes).

What is a scheme? Schemes are the basic building blocks of thinking. They are organized systems of actions or thought that allow us to mentally represent or “think about” the objects and events in our world. Schemes may be very small and specific (grasping, recognizing a square), or they may be larger and more general (using a map in a new city). People adapt to their environment as they increase and organize their schemes.

As children move from sensorimotor to formal-operational thinking, what are the major changes? Piaget believed that young people pass through four stages as they develop: sensorimotor, preoperational, concrete-operational, and formal-operational. In the sensorimotor stage, infants explore the world through their senses and motor activity, and they work toward mastering object permanence and performing goal-directed activities. In the preoperational stage, symbolic thinking and logical operations begin. Children in the stage of concrete operations can think logically about tangible situations and can demonstrate conservation, reversibility, classification, and seriation. The ability to perform hypothetico-deductive reasoning, coordinate a set of variables, and imagine other worlds marks the stage of formal operations.

How do neo-Piagetian and information processing views explain changes in children's thinking over time? Information processing theories focus on attention, memory capacity, learning strategies, and other processing skills to explain how children develop rules and strategies for making sense of the world and solving problems. Neo-Piagetian approaches also look at attention, memory, and strategies and at how thinking develops in different domains such as numbers or spatial relations. Research in neuroscience suggests that when learning a new skill, children move through three tiers—from *actions* to *representations* to *abstractions*. Within each tier, the pattern is moving from accomplishing a single action to mapping or coordinating two actions together such as coordinating addition and multiplication in math, to creating whole systems of understanding.

What are some limitations of Piaget's theory? Piaget's theory has been criticized because children and adults often think in ways that are inconsistent with the notion of invariant stages. It also appears that Piaget underestimated children's cognitive abilities; he insisted that children could not be taught the operations of the next stage but had to develop them on their own. Alternative explanations place greater emphasis on students' developing information processing skills and ways teachers can enhance their development. Piaget's work is also criticized for overlooking cultural factors in child development.

Vygotsky's Sociocultural Perspective (pp. 85–90)

According to Vygotsky, what are three main influences on cognitive development? Vygotsky believed that human activities must be understood in their cultural settings. He believed that our specific mental structures and processes can be traced to our interactions with others; that the tools of the culture, especially the tool of language, are key factors in development; and that the ZPD is where learning and development are possible.

What are psychological tools and why are they important? Psychological tools are signs and symbol systems such as numbers and mathematical systems, codes, and language that support learning and cognitive development. They change the thinking process by enabling and shaping thinking. Many of these tools are passed from adult to child through formal and informal interactions and teachings.

Explain how interpsychological development becomes intrapsychological development. Higher mental processes appear first between people as they are co-constructed during shared activities. As children engage in activities with adults or more capable peers, they exchange ideas and ways of thinking about or representing concepts. Children internalize these co-created ideas. Children's knowledge, ideas, attitudes, and values develop through appropriating, or “taking for themselves,” the ways of acting and thinking provided by their culture and by the more capable members of their group.

What are the differences between Piaget's and Vygotsky's perspectives on private speech and its role in development? Vygotsky's sociocultural view asserts that cognitive development hinges on social interaction and the development of language. As an example, Vygotsky describes the role of children's self-directed talk in guiding and monitoring thinking and problem solving, whereas Piaget suggests that private speech is an indication of the child's egocentrism. Vygotsky, more than Piaget, emphasized the significant role played by adults and more-able peers in children's learning. This adult assistance provides early support while students build the understanding necessary to solve problems on their own later.

What is a student's ZPD? At any given point in development, there are certain problems that a child is on the verge of being able to solve and others that are beyond the child's capabilities. The ZPD (zone of proximal development) is the place where the child cannot solve a problem alone but can succeed under adult guidance or in collaboration with a more advanced peer.

What are two criticisms or limitations of Vygotsky's theory? Vygotsky may have overemphasized the role of social interaction in cognitive development; children figure out quite a bit on their own. Also, because he died so young, Vygotsky was not able to develop and elaborate on his ideas. His students and others since have taken up that work.

Implications of Piaget's and Vygotsky's Theories for Teachers (pp. 90–95)

What is the “problem of the match” described by Hunt? The “problem of the match” is that students must be neither bored by work that is too simple nor left behind by teaching they

cannot understand. According to Hunt, disequilibrium must be carefully balanced to encourage growth. Situations that lead to unexpected results can help create an appropriate level of disequilibrium.

What is active learning? Why is Piaget's theory of cognitive development consistent with active learning? Piaget's fundamental insight was that individuals construct their own understanding; learning is a constructive process. At every level of cognitive development, students must be able to incorporate information into their own schemes. To do this, they must act on the information in some way. This active experience, even at the earliest school levels, should include both physical manipulation of objects and mental manipulation of ideas. As a general rule, students should act, manipulate, observe, and then talk and/or write about what they have experienced.

Concrete experiences provide the raw materials for thinking. Communicating with others makes students use, test, and sometimes change their thinking abilities.

What is assisted learning, and what role does scaffolding play? Assisted learning, or guided participation in the classroom, requires scaffolding—understanding the students' needs; giving information, prompts, reminders, and encouragement at the right time and in the right amounts; and then gradually allowing the students to do more and more on their own. Teachers can assist learning by adapting materials or problems to students' current levels, demonstrating skills or thought processes, walking students through the steps of a complicated problem, doing part of the problem, giving detailed feedback and allowing revisions, or asking questions that refocus students' attention.

MULTIPLE-CHOICE QUESTIONS

- Classes at Star Community High School began at 7:30 a.m. The new principal, however, wanted to start classes at a later time of 10:00 a.m. The principal submitted a proposal to the local education office and provided several reasons for the recommended change. Imagine you were the officer tasked to handle the proposal and to verify the reasons cited by the principal. In your review, you found that several of the reasons made claims that were not supported by research, EXCEPT:
 - Teenagers undergo neurological developments that reset their biological clock, making many of them unable to sleep before midnight, and hence, they would not get the ideal 9 hours of sleep if school started at 7:30 a.m.
 - Research consistently and conclusively shows that schools that start later in the day (e.g., 10:00 a.m.) have better academic performance than schools that begin early (e.g., 7:30 a.m.).
 - Schools that begin too early may lead many students to experience sleep deprivation, and sleep deprivation is related to failure in memory retrieval; so, performance would suffer.
 - It is better to give students more time for breakfast and less time for lunch, given that the former supplements students with nutrients needed to energize their day, while the latter generally leads to drowsiness in afternoon classes.
- Miss McClintock discovered that five of the children in her class were developmentally advanced. All of the students' language skills were exploding! Although many of the students still had trouble sharing, a few appeared to understand that by sharing, everyone could be happy. Finally, there was even one child who could solve conservation problems. According to Piagetian theory, in what stage are the students in Miss McClintock's class?
 - Formal operations
 - Concrete operations
 - Preoperational
 - Sensorimotor
- You want to maximize your students' learning outcomes and you recently read a book written by Vygotsky. Which of the following strategies would LEAST likely be employed by you?
 - Whenever appropriate, you will utilize technological tools and interactive devices to assist with your teaching.
 - You will put students in the same classroom into groups for discussions to facilitate their learning of challenging topics.
 - You will assign additional challenge questions at the end of each class and provide appropriate assistance to your students in solving these.
 - You will encourage students to think about certain problems and talk to themselves about the issues they are working on, before soliciting answers from them.
- Which of the following is TRUE about cognitive development and teaching?
 - Teachers should provide more social stimulations and reduce physical stimulations in the classroom because the former is more important for early cognitive development.
 - Students will benefit if most of their learning comes through direct instructions from a more experienced teacher.
 - Repeatedly teaching students what they already know is important to reinforce their memory and to consolidate their knowledge.
 - Providing students with challenging questions will not intimidate them, but keep them engaged, if appropriate supports are given.

CONSTRUCTED-RESPONSE QUESTIONS

Case

When planning for instruction, Mr. Gething remembered that students should be neither bored nor frustrated. Although this made sense to him, he was unsure how he would compensate for the diverse group of students he had in his second-period language arts class. Some students had difficulty with the English language, and other students planned to participate in the school's annual Shakespearean play. He knew that by grouping students of mixed ability, he could occasionally draw on the talents of his knowledgeable students to assist the less-advanced students. He also understood that without guidelines, students might not accomplish anything.

- Explain the theory of learning Mr. Gething is initially drawing on, and identify the individual credited with it.
- What is the term for the assistance that the more knowledgeable class members may provide to the less-advanced students in order to help them succeed? List some strategies these students might use to assist their peers.

MyLab Education Licensure Exam

▼ WHAT WOULD THEY DO?

TEACHERS' CASEBOOK: Symbols and Cymbals

Here is how several expert teachers said they would help their students understand abstract concepts.

LINDA GLISSON AND SUE MIDDLETON • Fifth-Grade Team Teachers

St. James Episcopal Day School, Baton Rouge, LA

To begin the lesson, I would have the students use a dictionary to define the word *symbolism* (root word—*symbol*) to discover that it means “something that stands for or represents something else.” I would then give them a brief “across the curriculum” exercise in ways they incorporate symbols and symbolism into their thinking every day. Examples follow. *Social studies, American history*: The American flag is just a piece of cloth. Why then do we recite a pledge to it? Stand at attention when it passes in a parade? What does it stand for? *English, literature—fables and fairy tales*: What does the wolf usually represent (stand for)? The lion? The lamb? *Art*: What color stands for a glorious summer day? Evil? Goodness and purity? I would continue with math symbols, scientific symbols, and music symbols and lead the students toward contributing other examples such as symbols representing holidays. I would then tell them about their own examples of symbolism that I had recorded. The students’ participation in and enthusiasm for the exercises would serve to determine whether they were ready for the material.

DR. NANCY SHEEHAN-MELZACK • Art and Music Teacher

Snug Harbor Community School, Quincy, MA

Even very young children can recognize symbols if the symbol is presented first and the explanation required second. A drawing of an octagon on a pole has always elicited the answer, “A stop sign,” whenever I have shown it. Children recognize symbols, but the teacher needs to work from their concrete knowledge to the more abstract concept, and there are a great many symbols in their daily life on which one can draw. Children as young as first-graders can recognize traffic sign shapes, letters

of the alphabet, and numbers, and further can recognize that they stand for directions, sounds, and how many. When they talk about these very common symbols, they can also realize they all use them for the same meaning.

VALERIE A. CHILCOAT • Fifth/Sixth-Grade Advanced Academics

Glenmount School, Baltimore, MD

Concrete examples of symbolism must come from the students’ own world. Street signs, especially those with pictures and not words, are a great example. These concrete symbols, however, are not exactly the same as symbolism used in poetry. The link has to be made from the concrete to the abstract. Silly poetry is one way to do this. It is motivating to the students to read or listen to, and it can provide many examples of one thing acting as another. This strategy can also be used in lower grades to simply expose children to poetry containing symbolism.

KAREN BOYARSKY • Fifth-Grade Teacher

Walter C. Black Elementary School, Hightstown, NJ

You can tell a lot about students’ thinking simply by interpreting their reactions. Knowing how to interpret students’ reactions is just as important as any other assessment tool you might use. In this case, it is clear that the students are confused about the concept of symbolism. This is a difficult concept even for many fifth-graders to understand and should be approached slowly. One approach to this topic would be to present students with pictures of familiar symbols, such as McDonald’s Golden Arches, the Nike Swoosh, or the Target logo. Students could attempt to explain what each of these symbols mean. A discussion about why manufacturers choose to use symbols instead of words would follow. Another approach would be to have the students interpret comparisons that use *like* or *as*. For example, “Sue is as pretty as a flower.” The teacher would guide the student to see that the author is using a flower to symbolize Sue’s looks.

chapter three

THE SELF, SOCIAL, AND MORAL DEVELOPMENT

WHAT WOULD YOU DO?

TEACHERS' CASEBOOK: Mean Girls

You have seen it before, but this year the situation in your middle school classroom seems especially vicious. A clique of popular girls has made life miserable for several of their former friends—who are now “rejects.” The discarded friends have committed the social sins of not fitting in—they wear the wrong clothes or aren’t “pretty” enough or aren’t interested in boys yet. To keep the status distinctions clear between themselves and “the others,” the popular girls spread gossip about their former friends, often disclosing the intimate secrets revealed when the “out” girls and the “in” girls were *best friends*—only a few months ago. Today, you discover that Stephanie, one of the rejected girls, has written a long, heart-baring e-mail to her former best friend, Alison, asking why Alison is “acting so mean.” The now-popular Alison forwarded the e-mail to the entire school, and Stephanie is humiliated. She has been absent for 3 days since the incident.

CRITICAL THINKING

- How would you respond to each of the girls?
- What—if anything—would you say to your other students?
- Are there ways you can address the issues raised by this situation in your classes?
- Reflecting on your years in school, were your experiences more like those of Alison or Stephanie?

Agsandrew/Shutterstock

OVERVIEW AND OBJECTIVES

Schooling involves more than cognitive development. As you think back on your years in school, what stands out—highlights of academic knowledge or memories of feelings, friendships, and fears? In this chapter, we examine the latter, which comprise personal, social, and moral development.

We begin by looking at a basic aspect of development that affects all the others—physical changes as students mature. Then we explore Urie Bronfenbrenner’s bioecological theory and use it as a framework for examining three major influences on children’s personal and social development: families, peers, and teachers. Families today have gone through many transitions, and these changes affect the roles of teachers. Next, we explore ideas about how we come to understand ourselves by looking at self-concept and identity, including racial-ethnic identity. Erikson’s psychosocial theory provides a lens for viewing these developments. Finally, we consider moral development. What factors determine our views about morality? What can teachers do to foster such personal qualities as honesty and cooperation? Why do students cheat in their academic work, and what can be done?

By the time you have completed this chapter, you should be able to:

- Objective 3.1 Describe general trends, group differences, and challenges in physical development through childhood and adolescence.
- Objective 3.2 Discuss how the components of Bronfenbrenner’s bioecological model influence development, especially the impact of families, parenting styles, peers, and teachers.
- Objective 3.3 Describe general trends and group differences in the development of identity and self-concept.
- Objective 3.4 Explain theories of moral development including those of Kohlberg, Gilligan, Nucci, and Haidt, and discuss how teachers can deal with one moral challenge for students—cheating.

OUTLINE

Teachers' Casebook—Mean Girls: What Would You Do?

Overview and Objectives

Physical Development

- Physical and Motor Development
- Play, Recess, and Physical Activity
- Reaching Every Student: Inclusive Athletics
- Challenges in Physical Development

Bronfenbrenner: The Social Context for Development

- The Importance of Context and the Bioecological Model
- Families
- Peers
- Reaching Every Student: Teacher Support
- Teachers and Child Abuse
- Society and Media

Identity and Self-Concept

- Erikson: Stages of Psychosocial Development
- Racial and Ethnic Identity
- Self-Concept
- Sex Differences in Self-Concept of Academic Competence
- Self-Esteem

Understanding Others and Moral Development

- Theory of Mind and Intention
- Moral Development
- Moral Judgments, Social Conventions, and Personal Choices
- Beyond Reasoning: Haidt's Social Intuitionist Model of Moral Psychology
- Moral Behavior and the Example of Cheating

Personal/Social Development: Lessons for Teachers

Summary and Key Terms

Teachers' Casebook—Mean Girls: What Would They Do?

PHYSICAL DEVELOPMENT

This chapter is about personal and social development, but we begin with a kind of development that is a basic concern of all individuals and families—physical development.

PUT YOURSELF IN THEIR PLACE How tall are you? What grade were you in when you reached that height? Were you one of the tallest or shortest students in your middle or high school, or were you about average? Did you know students who were teased because of something about their physical appearance? How important was your physical development to your feelings about yourself? •

Physical and Motor Development

For most children, at least in the early years, growing up means getting bigger and stronger, and becoming more coordinated. It also can be a frightening, disappointing, exciting, and puzzling time.

YOUNG CHILDREN. Preschool children are very active. Their *gross-motor* (large muscle) skills improve greatly during these early years. Between ages 2 and about 4 or 5, preschoolers' muscles grow stronger, their brains develop to better integrate information about movements, their balance improves, and their center of gravity moves lower, so they are able to run, jump, climb, and hop. By age 2, most children stop "toddling." Their awkward, wide-legged gait becomes smooth and rhythmic; they have perfected walking. During their third year, most children learn to run, throw, and jump, but these activities are not well controlled until age 4 or 5. Most of these movements develop naturally if the child has normal physical abilities and the opportunity to play. Children with physical problems, however, may need special training to develop these skills. And because they can't always judge when to stop, many preschoolers need interludes of rest scheduled after periods of physical exertion (Berk & Meyers, 2016; Thomas & Thomas, 2008).

Fine-motor skills such as tying shoes or fastening buttons, which require the coordination of small movements, also improve greatly during the preschool years. Children should be given the chance to work with large paintbrushes, fat pencils and crayons, big pieces of drawing paper, oversized Legos, and soft clay or play dough to accommodate

their current skills. During this time, children will begin to develop a lifelong preference for their right or left hand. By age 5, about 90% of students prefer their right hand for most skilled work, and 10% or so prefer their left hand, with more boys than girls being left-handed (R. S. Feldman, 2004; E. L. Hill & Khanem, 2009). Handedness is a genetically based preference, so don't try to make children switch. Some research even indicates that left-handed children are more likely than their right-handed peers to develop advanced verbal and mathematical skills (Berk & Meyers, 2016).

ELEMENTARY SCHOOL YEARS. During the elementary school years, physical development is fairly steady for most children. They become taller, leaner, and stronger, so they are better able to master sports and games. There is tremendous variation among

children, however. A particular child can be much larger or smaller than average and still be perfectly healthy. Because children at this age are very aware of physical differences but are not the most tactful people, you may overhear comments such as “You’re too little to be in third grade. What’s wrong with you?” or “How come you’re so fat?”

Throughout elementary school, many of the girls are likely to be as large as or larger than the boys in their classes. Between the ages of 11 and 14, girls are, on average, taller and heavier than boys of the same age. This size discrepancy can give girls an advantage in physical activities, but some girls may feel conflict over this and, as a result, downplay their physical abilities (Woolfolk & Perry, 2015).

THE ADOLESCENT YEARS. Puberty marks the beginning of sexual maturity. It is not a single event, but a series of changes involving almost every part of the body. The sex differences in physical development observed during the later elementary years become even more pronounced at the beginning of puberty. But these changes take time. The earliest visible signs of puberty in girls are the growth of nipples and budding of breasts at around age 9 for African American girls and 10 for European American and Canadian girls. At about the same time, boys’ testes and scrotums begin to grow larger. On average, between ages 12 and 13, girls have their first menstrual period (called **menarche**), but the range is from age 10 to 16½, with African American girls experiencing menarche about six months earlier on average than European American and Canadian girls. Boys have their first sperm ejaculation (called **spermarche**) between the ages of 12 to 14. Boys develop facial hair over the next several years, reaching their final beard potential by about age 18 or 19—with some exceptions who take longer to develop their final facial hair. Less-welcome changes in puberty are increases in skin oiliness, skin acne, and body odor.

Girls reach their final height around ages 14 to 16, several years ahead of boys. So there is a time in middle school, as in late elementary school, when many girls are taller than their male classmates. Most boys continue growing until about age 19, but both boys and girls can continue to grow slightly until about age 25 (Thomas & Thomas, 2008; Wigfield, Byrnes, & Eccles, 2006).

EARLY AND LATER MATURING. Psychologists have been particularly interested in the academic, social, and emotional differences between adolescents who mature early and those who mature later.

For girls, maturing way ahead of classmates can be a definite disadvantage. Being larger and more “developed” than everyone else your age is not a valued characteristic for girls in many cultures (D. C. Jones, 2004; Mendle & Ferrero, 2012). Early maturation is associated with emotional difficulties such as depression, anxiety, lower achievement in school, drug and alcohol abuse, unplanned pregnancy, suicide, greater risk of breast cancer in later life, and eating disorders, especially in societies that define thinness as attractive, at least for European American girls. Researchers have found fewer problems for early-maturing African American girls, but studies of these girls are limited (DeRose, Shiyko, Foster, & Brooks-Gunn, 2011; Stattin, Kerr, & Skoog, 2011).

The timing of maturation is not the only factor affecting girls; social influences are powerful too. In a study of Native American (United States) and First Nations (Canada) girls, Melissa Walls and Les Whitbeck (2011) found early maturing girls were more likely to abuse alcohol and drugs, but this association was influenced by social factors such as early dating and the attitudes of peers toward drugs. Maturing early can place girls in dating and friendship contexts where it is difficult to say no to drugs. Later maturing girls seem to have fewer problems, but they may worry that something is wrong with them, so adult reassurance and support are important.

Early maturity in males is associated with popularity. The early maturing boy’s taller, broad-shouldered body type fits the cultural stereotype for the male ideal. Even so, recent research points to more disadvantages than advantages for early maturation in boys. Early maturing boys tend to engage in more delinquent behavior—and this is true for White, African American, and Mexican American boys. They also appear to be at

Connect and Extend to PRAXIS II®

Human Development (I, A2)

Explain how development in one domain (e.g., physical, emotional) can affect development in other domains.

MyLab Education Video Example 3.1

Teenager Josh articulately describes some of the challenges that adolescents face, including his early maturation, a friend’s eating disorder, peer pressure, sexual relationships, and his after-school job.

Puberty The physiological changes during adolescence that lead to the ability to reproduce.

Menarche The first menstrual period in girls.

Spermarche The first sperm ejaculation for boys.

GUIDELINES

Dealing with Physical Differences in the Classroom

Address students' physical differences in ways that do not call unnecessary attention to the variations.

Examples

1. Try to seat smaller students so they can see and participate in class activities, but avoid seating arrangements that are obviously based on height.
2. Balance sports and games that rely on size and strength with games that reflect cognitive, artistic, social, or musical abilities, such as charades or drawing games.
3. Don't use, and don't allow students to use, nicknames based on physical traits.
4. In preschool classes, keep a good supply of left-handed scissors.

Help students obtain factual information on differences in physical development.

Examples

1. Set up science projects on sex differences in growth rates.
2. Have readings available that focus on differences between early and late maturers. Make sure that you present the positives and the negatives of each.

3. Find out the school policy on sex education and on informal guidance for students. Some schools, for example, encourage teachers to talk to girls who are upset about their first menstrual period, while other schools expect teachers to send the girls to talk to the school nurse (if your school still has one—budget cuts have eliminated many).
4. Give the students models in literature or in their community of accomplished and caring individuals who do not fit the culture's ideal physical stereotypes.

Accept that concerns about appearance and the opposite sex will occupy much time and energy for adolescents.

Examples

1. Allow some time at the end of class for socializing.
2. Deal with some of these issues in curriculum-related materials.

For more information about accommodations for physical differences in your classroom, see dos.claremontmckenna.edu/PhysicalLearningDiff.asp.

greater risk for depression, victimization by bullies, eating disorders, early sexual activity, and for abusing alcohol, illicit drugs, and cigarettes (Berk & Meyers, 2016; Mendle & Ferrero, 2012; Westling, Andrews, Hampson, & Peterson, 2008).

Boys who mature late may have a more difficult time initially because they are smaller and less muscular than the “ideal” for men (Harter, 2006). However, some studies show that in adulthood, males who matured later tend to be more creative, tolerant, and perceptive. Perhaps the trials and anxieties of maturing late teach these boys to be better problem solvers (Brooks-Gunn, 1988; Steinberg, 2014). All adolescents can benefit from knowing that there is a very wide range for timing and rates in “normal” maturation and that there are challenges for both early and late maturers. See the *Guidelines: Dealing with Physical Differences in the Classroom*.

Play, Recess, and Physical Activity

Maria Montessori once noted, “Play is children’s work,” and Piaget and Vygotsky would agree. The brain develops with stimulation, and play provides some of that stimulation at every age. In fact, some neuroscientists suggest that play might help in the important process of pruning brain synapses during childhood (Pellis, 2006). Other psychologists believe play allows children to experiment safely as they learn about their environment, try out new behaviors, solve problems, and adapt to new situations (Pellegrini, Dupuis, & Smith, 2007). Babies in the sensorimotor stage learn by exploring, sucking, pounding, shaking, throwing—acting on their environments. Preoperational preschoolers are beginning to play simple games with predictable rules. They love make-believe play and use pretending to form symbols, explore language, and interact with others.

Elementary school age children also like fantasy, but this fantasy play becomes more complex as children create characters and rules, for example, rules about how to bow to and obey the “Queen of everything.” They also are beginning to play more

complex games and sports, and thus learn cooperation, fairness, negotiation, and winning and losing as well as developing more sophisticated language. As children head toward adolescence, play, games, and sports continue to be part of their physical and social development (Woolfolk & Perry, 2015). Play is particularly important for both children's happiness and their social and cognitive development (Hopkins, Dore, & Lillard, 2015; Lillard et al., 2013).

CULTURAL DIFFERENCES IN PLAY. Consistent with so many other topics, there are cultural differences in play, as Vygotsky probably would emphasize. In some cultures, such as American or Turkish communities, adults, particularly mothers, often are play partners with their children. But in other cultures such as East Indian, Indonesian, or Mayan, adults are not seen as appropriate play partners for children; siblings and peers are the ones who teach younger children how to participate in play activities (Callaghan et al., 2011; Vandermass-Peler, 2002). In some families and cultures, children spend more time helping with chores and less time in solitary or group play.

There are characteristic forms of play across cultures: Alaska Native children tell dream stories, Chinese children fly kites, Cameroonian children hunt for mice (Berger, 2015), and my Californian granddaughter went through a period when she was Elsa from *Frozen* and I always had to be Anna. Now we discuss our favorite ponies from *My Little Pony* and do experiments as she teaches me to be a “scientist.” Different materials and “toys” are used as available in different cultural groups—everything from expensive video games to sticks, rocks, and banana leaves. Children use what their culture provides to play. Also, teachers in the United States and Australia may place less emphasis on the value of play for children's learning compared to teachers in other countries such as Norway, Sweden, New Zealand, and Japan, where a “play pedagogy” may be part of the curriculum (Lillemyr, Søbstad, Marder, & Flowerday, 2011; Synodi, 2010).

EXERCISE AND RECESS. Physical activity and participation in athletics have benefits for all students' health, well-being, leadership skills, social relationships, brain development, and even learning. Because most of today's children do not get much physical activity in their daily lives, schools have a role in promoting active play. There are good, academic reasons for recess and exercise. Exercise promotes blood flow and increased neurotransmitters in the brain, in addition to improving mood and helping students focus attention (Berger, 2015). Other researchers note that students in Asian countries, who consistently outperform U.S. students on international reading, science, and mathematics tests, have more frequent recess breaks throughout the school day. One study of 11,000 elementary students found that those who had daily recess of 15 minutes or longer every day were better behaved in class than students who had little or no recess. This was true even after controlling for student gender and ethnicity, public or private school setting, and class size (Barros, Silver, & Stein, 2009). Unfortunately, physical education (PE) time in the United States is being cut to allow for more academic time focused on test preparation (Ginsburg, 2007; Zhu, Boiarskaia, Welk, & Meredith, 2010). One strong caution in the call for more physical activity in schools: Research on concussions related to sports injuries indicates that full-impact contact sports should be avoided, at least for students under age 12 or so, and protective equipment is critical (Berger, 2015).

MyLab Education
Video Example 3.2

As this video suggests, recess, school sports, and lessons that include physical activity help to foster not only motor development but also social and cognitive skills. Physical activity and participation in athletics has benefits for all students' health, well-being, academic success, leadership skills, and their social relationships.

Reaching Every Student: Inclusive Athletics

The sports participation of students with disabilities is limited in most schools. Recess breaks may be especially important for students with attention-deficit hyperactive disorder (ADHD). If more breaks were provided, fewer students, especially boys, might be diagnosed with ADHD (Pellegrini & Bohn, 2005). But this could change. Federal laws state that schools have the legal obligation “to provide students with disabilities an equal opportunity to participate alongside their peers in after-school athletics and clubs. . . . [S]chools may not exclude students who have an intellectual, developmental, physical, or

any other disability from trying out and playing on a team, if they are otherwise qualified” (Duncan, 2013). Schools are not expected to change their standards for making or staying on a team, but they are expected to make reasonable accommodations, such as using a visual starter instead of a starting gun in races where a participant is deaf. Also, some sports participation for students with disabilities such as wheelchair basketball could be added to the extracurricular options.

One reason for concern about physical activity for children is the increase in childhood obesity, as you will see next.

Challenges in Physical Development

Physical development is public. Everyone sees how tall, short, heavy, thin, muscular, or coordinated you are. As students move into adolescence, they feel “on stage,” as if everyone is evaluating them; and physical development is part of what is being evaluated. So physical development also has psychological consequences (Thomas & Thomas, 2008).

OBESEITY. If you have seen the news lately, you know that obesity is a growing problem in America, especially for children. In fact, between 1980 and 2012, the percentage of children ages 6 to 11 who were obese increased from 7% to 18%, while the percentage of 12- to 19-year-olds who were obese increased from 5% to 21% (Centers for Disease Control, 2015a). Obesity usually is defined as being more than 20% heavier than average compared to others of the same age, sex, and body build. Figure 3.1 shows some state-by-state rates of obesity for high school students in the United States.

There is some good news, however. From 2004 to 2012, there was a significant decrease in obesity for preschool children (2 to 5 years old)—down from almost 14% to a little over 8% (Ogden, Carroll, Kit, & Flegal, 2014).

The consequences of obesity are serious for children and adolescents: diabetes, strain on bones and joints, respiratory problems, and a greater chance of heart problems and obesity as adults. Obesity also has negative effects for children’s play with friends or participation in sports, as children with obesity often are the targets of cruel teasing. Like

Source: Centers for Disease Control and Prevention. Map retrieved from <http://www.cdc.gov/healthyschools/obesity/obesity-youth.htm>

everything else involving children's development, this increase in obesity rates probably has many interacting causes including poor diet, genetic factors, increased hours sitting in front of screens (phones, computers, televisions, and tablets), and lack of exercise (Woolfolk & Perry, 2015).

Another challenge in physical development for many children involves not too much weight, but too little.

EATING DISORDERS. As they grow and their bodies change, many children become very concerned about their appearance. This has always been true, but today, the emphasis on fitness and beauty makes young people even more likely to worry about how their bodies “measure up” to the cultural ideals in Web posts, magazines, and films. New York City administrators acknowledged this widespread problem in 2013 with its Girls Project, geared toward girls ages 7 to 12 (Hartocollis, 2013; nyc.gov/html/girls/). Another project, GirlsHealth.gov, sponsored by the U.S. Office on Women's Health, provides resources for girls about body image, nutrition, relationships, and fitness. Their motto is “Be healthy. Be happy. Be you. Beautiful.”

Excessive concern with body image can be a factor in developing eating disorders such as **binge eating** (for example, eating an entire gallon of ice cream or a whole cake), **bulimia** (binge eating followed by purging, fasting, or excessive exercise to “undo” the binge) and **anorexia nervosa** (self-starvation). Eating disorders are the third most common chronic illnesses of adolescence and have the highest death rate if they are left untreated.

Binge eating is a more serious problem than simply overeating because bingeing is associated with significant physical and psychological problems. About 5% to 6% of the people in the United States suffer from binge eating disorders (American Psychiatric Association, 2013b; Golden et al., 2015). *Bulimia* is a related disorder. After bingeing, to avoid gaining weight, people force themselves to vomit or they use strong laxatives to purge themselves of the extra calories. Students with bulimia are hard to detect because they tend to maintain a normal weight, but their digestive systems can be permanently damaged from the purging. About 2% of the people in the United States have bulimia (Downs & Blow, 2013).

Anorexia affects about 1% of the U.S. population. It is even more dangerous than bulimia, because those with anorexia either refuse to eat or eat practically nothing while often exercising obsessively. In the process, they may lose 20% to 50% of their body weight, and some (about 5%) literally starve themselves to death (American Psychiatric Association, 2013b). In fact, 50 years of research confirms that the death rate from anorexia is higher than from any other psychological disorder. One in 5 deaths from anorexia is a suicide. Anorexic students become very thin, and may appear pale, have brittle fingernails, and develop fine dark hairs all over their bodies. They are easily chilled because they have so little fat to insulate their bodies. They often are depressed, insecure, moody, and lonely. Girls may stop having their menstrual period (Arcelus, Mitchell, Wales, & Nielsen, 2011; Downs & Blow, 2013; Sutamiariya, Arseniev, & Moreno, 2016).

Eating disorders are becoming more common, sometimes encouraged and supported by pro-ana (pro-anorexia nervosa) and pro-ima (pro-bulimia) social networks, blogs, Twitter posts, and Web sites. The pro-ana and pro-ima movements often are militant in their support of the “choice” of anorexia or bulimia as a “lifestyle” (Casilli, Tubaro, & Araya, 2012). The related digital media supports eating disorders by providing photographs or videos of very thin models, ideas for rapid weight loss and ways of concealing it, motivational statements and social support, virtual communities and online discussions, a sense of belonging to a special group that understands you—the only place to be “real” (Peebles et al., 2012; Rodgers, Skowron, & Chabrol, 2011). Pro-ana Web sites are available in many countries and languages; for example, almost 300 sites existed in 2012 in the French language alone (Casilli, Pailler, & Tubaro, 2013). In 2012, Tumblr and Pinterest decided to ban all “thinspiration” content—the sharing of motivational images and messages about unhealthy weight loss (Casilli et al., 2013).

Binge eating Uncontrolled eating of large quantities of food, such as a whole cake or entire jar of peanut butter.

Bulimia Eating disorder characterized by overeating, then getting rid of the food by self-induced vomiting or laxatives.

Anorexia nervosa Eating disorder characterized by very limited food intake.

GUIDELINES

Supporting Positive Body Images in Adolescents

Listen to adolescents talk about their health.

Examples

1. If they mention wanting to lose weight, seize the opportunity to talk about healthy weight, body image, and cultural influences on youth.
2. If they mention diets they or their friends are trying, provide them with nutritionally sound information about myths, misinformation, and dangers related to fad diets.
3. In general, be attentive. An adolescent may make a brief comment that could serve as a terrific entrance into a valuable conversation about body image.

Ask questions.

Examples

1. Are you concerned about your weight (or shape or size) at all? Do you think your friends are concerned about their weight? Do you or your friends talk a lot about your weight?
2. Do you know that diets are the worst way to lose or maintain weight? Have you ever dieted? Why?

3. Do you know that eating only low-fat or fat-free foods is NOT healthy eating? Do you know that you need fat in your diet and that without it you can have all kinds of health problems?

Make available resources for adolescents who have body image issues.

Examples

1. Have accurate, youth-oriented resources available to read, look up on the Internet, or find in a library.
2. Encourage youth to continue conversations about these issues with you, their parents, a health professional, a trusted teacher, or a caring, knowledgeable adult.
3. Deal with some of these issues in curriculum-related materials.

For more information about adolescents and body image, see epi.umn.edu/let/pubs/img/adol_ch13.pdf

Source: Based on Story, M., & Stang, J. (2005). Nutrition Needs of Adolescents. In J. S. M. Story (Ed.), *Guidelines for Adolescent Nutritional Services* (pp. 158–159). Minneapolis, MN: University of Minnesota.

Students dealing with these issues usually require professional help. Don't ignore the warning signs: Less than one-third of people with eating disorders actually receive treatment (Stice & Shaw, 2004). A teacher may be the person who begins the chain of help for students with these tragic problems. See the *Guidelines: Supporting Positive Body Images in Adolescents*.

People certainly are more than physical bodies. The rest of this chapter is about personal and moral development, beginning with a theoretical frame to put that development in context.

MyLab Education **Self-Check 3.1**

BRONFENBRENNER: THE SOCIAL CONTEXT FOR DEVELOPMENT

We put the developing person in context by exploring the work of Urie Bronfenbrenner (1917–2005), who was born in Moscow, Russia, but moved with his family to the United States when he was 6. Bronfenbrenner completed a double major in psychology and music at Cornell in 1938 and a PhD in psychology from the University of Michigan in 1942. Over his long career in psychology, he worked as a clinical psychologist in the U.S. Army and as a professor at the University of Michigan and at Cornell. He also helped to found the Head Start early childhood program.

The Importance of Context and the Bioecological Model

“Students typically do not learn alone but rather in collaboration with their teachers, in company with their peers, and with encouragement of their families” (Durlak, Weissberg, Dymnicki, Taylor, & Schellinger, 2011, p. 405). Teachers, families, and peers are part of

the students' context. **Context** is the total situation that surrounds and interacts with an individual's thoughts, feelings, and actions to shape development and learning. Contextual effects on the developing individual are both internal and external. For example, hormone levels within the body are contexts for developing organs, including the brain, as well as for adolescents' self-concepts during puberty. The focus of this book, however, is the contexts outside the person. Children grow up in families and are members of particular ethnic, language, religious, and economic communities. They live in neighborhoods, attend schools, and are members of classes, teams, glee clubs, or even gangs. Social and educational programs, along with the policies of governments, affect their lives. These contexts influence the development of behaviors, beliefs, and knowledge by providing resources, supports, incentives and punishments, expectations, teachers, models, tools—all the building blocks of learning and development (Chiu & Chow, 2015; Dodge, 2011; Lerner, Theokas, & Bobek, 2005).

Contexts also affect how actions are interpreted. For example, if a stranger approaches a 7-month-old infant, the baby is likely to cry if the setting is unfamiliar, but she may not cry if the stranger is in her home. Adults are more likely to help a stranger in need in small towns as opposed to larger cities (J. Kagan & Herschkowitz, 2005). Think about hearing a telephone ring. Is it 3:00 in the afternoon or 3:00 in the morning? Did you just call someone and leave a message asking for a return call? Has the phone been ringing off the hook, or is this the first call in days? Did you just sit down to dinner? The meaning of the ring and the feelings you have will vary, depending on the context.

Urie Bronfenbrenner's **bioecological model** of development (Bronfenbrenner, 1989; Bronfenbrenner & Morris, 2006) recognizes that the physical and social contexts in which we develop are *ecosystems* because they are constantly interacting with and influencing each other. Look at Figure 3.2 on the next page. Every person lives within a *microsystem*, inside a *mesosystem*, embedded in an *exosystem*, all of which are a part of the *macrosystem*—like a set of Russian painted dolls, nested one inside the other. In addition, all development occurs in and is influenced by the time period—the *chronosystem*.

In the *microsystem* are the activities, roles, and relationships that the individual experiences in face-to-face settings. For children, the *microsystem* might be the immediate family, friends, or teachers, the activities of play and school, and their roles as family members and as students. Relationships in the *microsystem* are reciprocal; they flow in both directions. The child affects the parent, and the parent influences the child, for example. The *mesosystem* is the set of interactions and relationships among all the elements of the *microsystem*—the family members interacting with each other or with the teacher. Again, all relationships are reciprocal; the teacher influences the parents, and the parents affect the teacher, and these interactions affect the child. The *exosystem* includes all the social settings that affect the child, even though the child is not a direct member of these systems. Examples are the teachers' relations with administrators and the school board; the parents' jobs; the community resources for health, employment, or recreation; or the family's religious affiliation. The *macrosystem* is the larger society—its values, laws, policies, conventions, and traditions (P. H. Miller, 2016).

Families

The first context for child development is the mother's womb. Scientists are learning more about the effects of this first environment—the expectant mother's general health, her level of stress; her nutrition; her exercise habits; her exposure to diseases like rubella and Zika; and her smoking, alcohol, and drug intake—on the infant's development. Clearly, the influence of the family begins before birth, but many new influences follow (Woolfolk & Perry, 2015).

FAMILY STRUCTURE. In the United States, the proportion of children growing up in a home with just one parent has doubled since the 1970s, from about 12% to more than 26%, while the percentage of children living with two married parents has decreased from about 85% to around 65% (Child Trends Databank, 2015). Increasingly, children

Context Internal and external circumstances and situations that interact with the individual's thoughts, feelings, and actions to shape development and learning. The physical or emotional backdrop associated with an event.

Bioecological model Bronfenbrenner's theory describing the nested social and cultural contexts that shape development. Every person develops within a *microsystem*, inside a *mesosystem*, embedded in an *exosystem*, all of which are a part of the *macrosystem* of the culture. All development occurs in and is influenced by the time period—the *chronosystem*.

FIGURE 3.2

URIE BRONFENBRENNER'S BIOECOLOGICAL MODEL OF HUMAN DEVELOPMENT

Every person develops within a *microsystem* (family, friends, school activities, teacher, etc.) inside a *mesosystem* (the interactions among all the microsystem elements), embedded in an *exosystem* (social settings that affect the child, even though the child is not a direct member—community resources, parents' workplace, etc.); all are part of the *macrosystem* (the larger society with its laws, customs, values, etc.). All development occurs in and is influenced by the time period—the *chronosystem*.

today may be part of **blended families**, with stepbrothers or stepsisters who move in and out of their lives. Some children live with an aunt, with grandparents, with one parent, in foster or adoptive homes, or with an older brother or sister. In some cultures such as Asian, Latin American, or African, children are more likely to grow up in **extended families**, with grandparents, aunts, uncles, and cousins living in the same household or at least in daily contact with each other. In addition, as many as 6,000,000 American children and adults have a gay or lesbian parent (Gates, 2013). The best advice is to avoid the phrases “your parents” and “your mother and father” and instead to speak of “your family” when talking to students.

No matter who is doing the parenting, research has identified characteristic differences in parents' styles.

PARENTING STYLES. One well-known description of **parenting styles** is based on the research of Diane Baumrind (1971, 1996, 2005, Baumrind, Larzelere, & Owens, 2010). In the late 1960s and early 1970s, her early work focused on a careful longitudinal study of 100 (mostly European American, middle-class) preschool children from California. Through observation of children and parents and interviews with parents, Baumrind

Blended families Parents, children, and stepchildren merged into families through remarriages.

Extended families Different family members—grandparents, aunts, uncles, cousins, and so on—living in the same household or at least in daily contact with the children in the family.

Parenting styles The ways of interacting with and disciplining children.

and the other researchers who built on her findings identified four parenting styles based on the parents' high or low levels of warmth and control, their expectations for maturity, and their ability to grant autonomy:

- *Authoritative parents* (high warmth, high control, high expectations, support for autonomy) set clear limits, enforce rules, and encourage mature behavior. But they are warm with their children. They listen to concerns, give reasons for rules, forgive mistakes, and allow more democratic decision making. There is less strict punishment and more guidance. Parents help children think through the consequences of their actions.
- *Authoritarian parents* (low warmth, high control, high expectations, low autonomy) seem cold and controlling in their interactions with their children. The children are expected to be mature and to do what the parent says, "Because I said so!" There is not much talk about emotions. Punishments are strict, but not abusive. The parents love their children, but they are not openly affectionate.
- *Permissive parents* (high warmth, low control, low expectations, high autonomy) are warm and nurturing, but they have few rules or consequences for their children and expect little in the way of mature behavior because "They're just kids." These parents are sometimes called *indulgent* because they hide their frustration, listen to their children no matter how disrespectful they might be, and make sacrifices to buy the children whatever they want.
- *Rejecting/Neglecting/Uninvolved parents* (low warmth, low control, indifferent about expectations and autonomy) don't seem to care at all and can't be bothered with controlling, communicating, or teaching their children.

Authoritarian, authoritative, and permissive parents love their children and are trying to do their best; they simply have different ideas about the best ways to parent. In broad strokes, there are differences in children's feelings and behavior associated with these three parenting styles. At least in European American, middle-class families, children of *authoritative* parents are more likely to do well in school, be happy with themselves, and relate well to others. Children of *authoritarian* parents are more likely to feel unhappy, guilty, or depressed and to rebel in adolescence. Children of *permissive* parents or the extreme, *indulgent* parents, may have trouble interacting with peers—they are used to having their way. Finally, children of *neglectful* parents tend to be immature, sad, lonely, and at risk for abuse. Both indulgent and rejecting/neglecting/uninvolved parenting styles can be harmful (Berger, 2015; Spera, 2005).

CULTURE AND PARENTING. In cultures that have a greater respect for elders and a more group-centered rather than individualist philosophy, it may be a misreading of the parents' actions to perceive their demand for obedience as "authoritarian" (Lamb & Lewis, 2005; Nucci, 2001). In fact, research by Ruth Chao (2001; Chao & Tseng, 2002) has challenged Baumrind's conclusions for Asian families. Chao finds that an alternative parenting style of *chiao shun* (a Chinese term that Chao translates as "training") better characterizes parenting in Asian and Asian American families. In addition, parenting that is more authoritarian—strict and directive, with clear rules and consequences—combined with high levels of warmth and emotional support, is associated with higher academic achievement and greater emotional maturity for inner-city children (P. W. Garner & Spears, 2000; Jarrett, 1995). Differences in cultural values and also in the danger level of some urban neighborhoods may make tighter parental control appropriate, and even necessary (Smetana, 2000).

Research with Latino parents also suggests that Baumrind's parenting styles are not helpful in understanding Latino families, in part because respect for adult authority is not associated with cold parent-child relationships in these families. Instead, adult authority and caring (*carino*) go hand-in-hand (Berger, 2015). Whatever the structure of the families you work with, see the *Guidelines: Family and Community Partnerships* on the next page for making connections.

Connect and Extend to PRAXIS II®

Families (I, B6)

Understand the influence of families, their culture, and values on student learning.

GUIDELINES

FAMILY AND COMMUNITY PARTNERSHIPS

Connecting with Families

1. Work with families to co-create methods for family involvement. Offer a range of possible participation methods. Make sure the plans are realistic and fit the lives of the families you are dealing with.
2. Remember that some students' families have had negative experiences with schools or may fear or mistrust schools and teachers. Find other places to collaborate: before or after ball games, or at a local church or recreation center. Go where families go; don't always expect them to come to school.
3. Maintain regular home-school contact through telephone calls or notes. If a family has no telephone, identify a contact person (relative or friend) who can take messages. If literacy is a problem, use pictures, symbols, and codes for written communication.
4. Make all communications positive, emphasizing growth, progress, and accomplishments.
5. With the families, design family-student celebrations of the student's efforts and successes (a movie, special meal, trip to the park or library, or treats such as ice cream and pizza).
6. On a regular basis, send home a note in word or picture form that describes the student's progress. Ask families to indicate how they celebrated the success and to return the note.
7. Follow up with a telephone call to discuss progress, answer questions, solicit family suggestions, and express appreciation for the families' contributions.
8. Make sure families feel welcome if they visit the classroom.

For more information on family school partnerships, see <http://www.hfrp.org/family-involvement>

Ginsburg, *Journal of Educational Psychology*, 87, pp. 272–281. Copyright © 1995 by the American Psychological Association. Adapted with permission of the APA.

ATTACHMENT. The emotional bond that forms between people is called **attachment**. Children in every culture form first attachments with parents or caregivers, even though people in different cultures may nurture attachments in different ways. For example, mothers in Uganda massage their infants, but do not kiss them. What a difference from the custom in the United States, where a picture of a baby circulated on Facebook highlights the frequency of kissing infants in the U.S.—the baby was covered in lipstick and the caption read, "Grandma is visiting" (Berger, 2015; R. A. Thompson & Raikes, 2003).

The quality of this attachment bond appears to have implications for forming relationships throughout life. Children who form what are called *secure attachments* with caregivers receive comfort when needed and are more confident to explore their world, perhaps because they know they can count on the caregiver. Children who form *insecure-avoidant*, *resistant*, or *disorganized attachments* can be fearful, sad, anxious, clinging, rejecting, confused, or angry in interactions with the caregivers. Some research indicates that authoritarian parenting styles are related to forming insecure attachments, but as we saw earlier, many factors influence the effects of parenting styles (Roeser, Peck, & Nasir, 2006).

The quality of attachment has implications for teachers. For example, in preschools, children who have formed secure attachments with parents/caregivers are less dependent on teachers and can interact with other children appropriately. Secure attachment is positively related to achievement test scores, teacher assessments of social competence throughout the school years, and even to lower dropout rates (Roeser et al., 2006). As we will see later, researchers are currently examining students' attachment to teachers and schools as a positive force in their lives.

DIVORCE. The divorce rate in the United States is one of the highest in the world. Some analysts estimate that between 40% and 50% of first-time marriages that took place in the 1990s will end in divorce—and the divorce rate is even higher for second and third marriages (P. R. Amato, 2001; Schoen & Canudas-Romo, 2006; Stanley, 2015). But those rates are different depending on your location, as you can see in Figure 3.3. What is the rate of divorce and remarriage like in your area?

Attachment Forming an emotional bond with another person, initially a parent or family member.

FIGURE 3.3

RATES OF DIVORCE AND REMARRIAGE BY STATE

By metropolitan areas, percentage of married people 15 years old and older who have married two or more times.

Source: From Lewis, J., M. & Kreider, R. M. (2015, March). *Remarriage in the United States: America community Survey Reports*. U.S. Census Bureau. Available at <https://www.census.gov/content/dam/Census/library/publications/2015/acs/acs-30.pdf>

As too many of us know from experiences in our own families, separation and divorce are stressful events for all participants, even under the best circumstances. The actual separation of the parents may have been preceded by years of conflict in the home or may come as a shock to all, including friends and children. During the divorce itself, conflict may increase as property and custody rights are being negotiated. After the divorce, more changes may disrupt the child's life as the custodial parent moves to a new neighborhood or works longer hours. For the child, this can mean leaving behind important friendships in the old neighborhood or school, just when support is needed the most. Even in those rare cases where there are few conflicts, ample resources, and the continuing support of friends and extended family, divorce is never easy for anyone. But it can be a better alternative for children than growing up in a home filled with conflict and discord. "Destructive conflict in any type of family undermines the well-being of parents and children" (Hetherington, 2006, p. 232).

GUIDELINES

Helping Children of Divorce

Take note of any sudden changes in behavior that might indicate problems at home.

Examples

1. Be alert to physical symptoms such as repeated headaches or stomach pains, rapid weight gain or loss, fatigue, or excess energy.
2. Be aware of signs of emotional distress such as moodiness, temper tantrums, or difficulty in paying attention or concentrating.
3. Let parents know about the students' signs of stress.

Talk individually to students about their attitude or behavior changes. This gives you a chance to find out about unusual stress such as divorce.

Examples

1. Be a good listener. Students may have no other adult willing to hear their concerns.
2. Let students know you are available to talk, and let the student set the agenda.

Watch your language to make sure you avoid stereotypes about "happy" (two-parent) homes.

Examples

1. Simply say "your families" instead of "your mothers and fathers" when addressing the class.
2. Avoid statements such as "We need volunteers for room mother" or "Your father can help you."

Help students maintain self-esteem.

Examples

1. Recognize a job well done.
2. Make sure the student understands the assignment and can handle the workload. This is not the time to pile on new and very difficult work.

3. The student may be angry with his or her parents, but may direct the anger at teachers. Don't take the student's anger personally.

Find out what resources are available at your school.

Examples

1. Talk to the school psychologist, guidance counselor, social worker, or principal about students who seem to need outside help.
2. Consider establishing a discussion group, led by a trained adult, for students whose parents are going through a divorce.

Be sensitive to both parents' rights to information.

Examples

1. When parents have joint custody, both are entitled to receive information and attend parent-teacher conferences.
2. The noncustodial parent may still be concerned about the child's school progress. Check with your principal about state laws regarding the noncustodial parent's rights.

Be aware of long-term problems for students moving between two households.

Examples

1. Books, assignments, and gym clothes may be left at one parent's house when the student is currently on visitation with the other parent.
2. Parents may not show up for their turn to pick up their child at school or may miss a parent-teacher conference because the note never got home.

For ideas about helping children adjust to divorce, see: <http://extension.missouri.edu/p/GH6611>

The first 2 years after the divorce seem to be the most difficult period for both boys and girls and especially hard for young adolescents (ages 10 to 14). Divorce can be harder on boys than girls, in part because mothers still tend to get custody of children, which leaves boys without a male role model in the house (Fuller-Thomson & Dalton, 2011). Children may have problems in school or just skip school, lose or gain an unusual amount of weight, have trouble sleeping, or experience other difficulties. However, adjustment to divorce is an individual matter; some children respond with increased responsibility, maturity, and coping skills (P. R. Amato, 2006; American Psychological Association, 2004; Arkes, 2015). See the *Guidelines: Helping Children of Divorce*.

Peers

Children also develop within peer groups. Rubin and his colleagues distinguish between two kinds of peer groups: cliques and crowds (Rubin, Coplan, Chen, Buskirk, & Wojslawowicz, 2005).

CLIQUEs. *Cliques* are relatively small, friendship-based groups (typically between three and a dozen members); they are more evident in middle childhood and early adolescence. These cliques typically include peers of the same sex and age who share common interests and engage in similar activities. Cliques serve young peoples' emotional and security needs by providing a stable social context in which group members know each other well and form close friendships (B. B. Brown, 2004; Henrich, Brookmeyer, Shrier, & Shahar, 2006).

PUT YOURSELF IN THEIR PLACE Think back to high school—did you have friends in any of these groups: geeks, populars, brains, jocks, partyers, emos, druggies, others? What were the main “crowds” at your school? How did your friends influence you? •

CROWDS. *Crowds* are less intimate, more loosely organized groups based on shared interests, activities, attitudes, or reputations. Even though they may go by different names in different schools, the most common crowds are *jocks*, *brains*, *nerds*, *druggies*, *goths*, *emos*, *populars*, *normals*, *nobodies*, and *loners*. Students don't necessarily *join* crowds; they are associated with or *assigned to* crowds by other students based on reputations and stereotypes (J. L. Cook & Cook, 2014). In fact, crowd members may or may not interact with one another. Association with crowds occurs during early and middle adolescence (Rubin et al., 2005). W. Andrew Collins and Laurence Steinberg (2006, p. 1022) call crowds “an identity ‘way station’ or placeholder during the period between individuation from parents and establishment of a coherent personal identity.”

Crowds become far less prominent in late adolescence. Interestingly, adolescents who are relatively more confident in their identity tend not to value crowd affiliations as much as those who are still exploring, and by high school, many adolescents believe affiliations with particular crowds stifle their identity and self-expression (W. A. Collins & Steinberg, 2006).

PEER CULTURES. At any age, students who have a set of “rules”—how to dress, talk, style their hair, and interact with others—are called **peer cultures**. The group, crowd, or clique determines which activities, music, or other students are in or out of favor. For example, when Jessica, a popular high school student, was asked to explain the rules that her group lives by, she had no trouble:

OK. No. 1: clothes. You cannot wear jeans any day but Friday, and you cannot wear a ponytail or sneakers more than once a week. Monday is fancy day—like black pants or maybe you bust out with a skirt. You have to remind people how cute you are in case they forgot over the weekend. No. 2: parties. Of course we sit down and discuss which ones we're going to because there is no point in getting all dressed up for a party that's going to be lame. (Talbot, 2002, p. 28)

These peer cultures encourage conformity to the group rules. When another girl in Jessica's group wore jeans on Monday, Jessica confronted her: “Why are you wearing jeans today? Did you forget it was Monday?” (Talbot, 2002, p. 28). Jessica explained that the group had to suspend this “rebel” several times, not allowing her to sit with them at lunch.

To understand the power of peers, we have to look at situations where the values and interests of parents clash with those of peers, and then observe whose influence dominates. In these comparisons, peers usually win in matters of style and socializing. Parents and teachers still are influential in matters of morality, career choice, and religion (J. R. Harris, 1998). Also, not all aspects of peer cultures are bad or cruel. The norms in some groups are positive and support achievement in school.

FRIENDSHIPS. Friendships are central to students' lives at every age. When there has been a falling-out or an argument, when rumors are started and pacts are made to ostracize someone (as with Alison and Stephanie at the beginning of the chapter or the “rebel” who wore jeans on Monday), the results can be devastating. In addition to

MyLab Education
Video Example 3.3

Young children often say that their friends are the people they play with. Grade schoolers like the girl shown here, typically describe friendships by mentioning shared activities. Older children and teens are more likely than younger children to mention specific traits and interests. Both convey that friends support you and are there for you.

Peer cultures Groups of children or adolescents with their own rules and norms, particularly about such things as dress, appearance, music, language, social values, and behavior.

causing the immediate trauma of being “in” or “out” of the group, peer relationships influence students’ motivation and achievement in school (Chiu & Chow, 2015; A. Ryan, 2001). In one study, sixth-grade students without friends showed lower levels of academic achievement, fewer positive social behaviors, and more emotional distress, even 2 years later, than students with at least one friend (Wentzel, Barry, & Caldwell, 2004). The characteristics of friends and the quality of the friendships matter, too. Having stable, supportive relationships with friends who are socially competent and mature enhances social development, protects students with emotional problems, and supports students during difficult times such as parents’ divorce or transition to new schools (W. A. Collins & Steinberg, 2006).

But the influence of friendships is not always positive. Based on a classic 3-year study that surveyed 20,000 high school students in Wisconsin and California, Steinberg (1998) found that 1 in every 5 students said that their friends made fun of people who tried to do well in school and about 40% of the students were just going through the motions of learning. This lack of investment was due in part to peer pressure because for many adolescents, “peers—not parents—are the chief determinants of how intensely they are invested in school and how much effort they devote to their education” (p. 331).

POPULARITY. What does it mean to be popular? We could answer this question by observing students or by using ratings from parents or teachers. But the most common way to assess popularity is to ask the students themselves two questions: Is this child liked? and What is this child like? Based on answers to these questions, we can identify four categories of children (see Table 3.1).

TABLE 3.1 • What Does It Take to Be Popular?

POPULAR CHILDREN
<i>Popular prosocial children:</i> These children are both academically and socially competent. They do well in school and communicate easily with peers. When they disagree with other children, they respond appropriately and have effective strategies for working things out. <i>Popular antisocial children:</i> This subgroup of children often includes boys who are aggressive. They may be athletic, and other children tend to think they are “cool” in the ways they bully other children and defy adult authority.
REJECTED CHILDREN
<i>Rejected aggressive children:</i> High rates of conflict and hyperactivity/impulsivity characterize the behaviors of this subgroup. These children have poor perspective-taking skills and self-control. They often misunderstand the intentions of others, assign blame, and act aggressively on their angry or hurt feelings. <i>Rejected withdrawn children:</i> These children are timid and withdrawn, often the targets of bullies. They are often socially awkward and withdraw from social interactions to avoid being scorned or attacked.
CONTROVERSIAL CHILDREN
As the descriptor implies, <i>controversial children</i> have both positive and negative social qualities and, as a result, their social status can change over time. They can be hostile and disruptive in some situations and then engage in positive prosocial behaviors in others. These children have friends and are generally happy with their peer relationships.
NEGLECTED CHILDREN
Perhaps surprisingly, most <i>neglected children</i> are well adjusted and they are not less socially competent than other children. Peers tend to view them as shy, but they don’t report being lonely or unhappy about their social lives. Apparently they don’t experience the extreme social anxiety and wariness that withdrawn children do.

Source: Woolfolk, A. & Perry, N. E. (2015). *Child and Adolescent Development* (2nd Ed.). Reprinted by permission of Pearson Education.

As you can see in Table 3.1, children identified as *popular* (highly rated) may behave in positive or negative ways. Children identified as *rejected* probably merit their low ratings because they are aggressive, immature, socially unskilled, or withdrawn. Children identified as *controversial* get mixed reviews; they display both positive and negative social behaviors. Finally, children identified as *neglected* are almost invisible—their peers simply do not mention them—but there is no consistent evidence that neglected children are anxious or withdrawn (Rubin et al., 2015).

CAUSES AND CONSEQUENCES OF REJECTION. Children and adolescents are not always tolerant of differences. About 5% to 10% of children are victims of rejection, bullying, and other difficulties (Boivin et al., 2013). In this section we are talking about *rejected* children. We will examine the very real and dangerous problems of bullying and cyberbullying in Chapter 13.

New students who are physically, intellectually, ethnically, racially, economically, or linguistically different may be rejected in classes with established cliques or crowds. Students who are aggressive, withdrawn, and inattentive-hyperactive are more likely to be rejected. But classroom context matters too, especially for aggressive or withdrawn students. In classrooms where the general level of aggression is high, being aggressive is less likely to lead to peer rejection. And in classrooms where solitary play and work are more common, being withdrawn is not as likely to lead to rejection. Thus, part of being rejected is just being too different from the norm. Also, being more attractive or engaging in prosocial behaviors such as sharing, cooperating, and friendly interactions are associated with peer acceptance, no matter what the classroom context.

If students are rejected or are victims of aggression, they may develop emotional problems such as depression or thoughts of suicide, behavioral or physical health problems, and difficulties in school (Boivin et al., 2013). Rejected children are less likely to participate in classroom learning activities, so their achievement suffers; they are more likely to drop out of school as adolescents. Problems persist over time. In their review of 17 studies that followed children into adulthood, Patricia McDougall and Tracy Vailancourt (2015) concluded, “there is evidence of a direct path between childhood peer victimization and poor long-term outcomes in adulthood” (p. 304). The strongest evidence was for heavy smoking for men and suicide for both men and women. In addition, rejected aggressive students are more likely to commit crimes as they grow older (Buhs, Ladd, & Herald, 2006). A teacher should be aware of how each student gets along with the group. Are there outcasts? Careful adult intervention can often correct such problems, especially at the late elementary and middle school levels, as we will see next (Pearl, Leung, Acker, Farmer, & Rodkin, 2007).

Sometimes rejection becomes aggression.

AGGRESSION. Aggression should not be confused with assertiveness, which means affirming or maintaining a legitimate right. Saying, “You are sitting in my chair!” is assertive. Pushing the invader out of the chair is aggressive. There are several forms of aggression. The most common form is **instrumental aggression**, which is intended to gain an object or privilege, such as shoving to get a chair or snatching a phone from another student. The intent is to get what you want, not to hurt the other student, but the hurt may happen anyway. A second kind is **hostile aggression**—inflicting intentional harm. Hostile aggression can take the form of either **overt aggression**, such as threats or physical attacks (as in, “I’m gonna beat you up!”), or **relational aggression**, which involves threatening or damaging social relationships (as in, “I’m never going to speak to you again!”). Boys are more likely to use overt aggression, and girls, like Alison in the opening case, are more likely to use relational aggression, especially in middle school and beyond (Ettekal & Ladd, 2015; Ostrov & Godleski, 2010). Students who use both relational aggression and overt physical aggression are at the greatest risk for negative consequences such as rejection, depression, and school failure. But students who use aggression strategically and not too often may be among the popular crowd—respected as powerful and “cool” (Ettekal & Ladd, 2015).

Instrumental aggression

Strong actions aimed at claiming an object, place, or privilege—not intended to harm, but may lead to harm.

Hostile aggression Bold, direct action that is intended to hurt someone else; unprovoked attack.

Overt aggression A form of hostile aggression that involves physical attack.

Relational aggression A form of hostile aggression that involves verbal attacks and other actions meant to harm social relationships.

A final kind of hostile aggression is a growing concern today, **cyber aggression**—using email, Twitter, Instagram, Snapchat, Facebook, or other social media to spread rumors, make threats, or otherwise terrorize peers, as Alison did in the case at the beginning of this chapter.

Children with more serious conduct problems often are identified during elementary school. Usually these problems are not new; they have been there for years (Petitclerc, Boivin, Dionne, Zoccolillo, & Tremblay, 2009), so waiting for children to “outgrow” aggressive behaviors does not work. For example, one study in Finland asked teachers to rate students’ aggression by answering “never,” “sometimes,” or “often” to statements such as “hurts another child when angry.” Teacher-rated aggression when students were age 8 predicted school adjustment problems in early adolescence and long-term unemployment in adulthood (Kokko & Pulkkinen, 2000). Similar results were found in a study conducted in Canada, New Zealand, and the United States. Boys (but not girls) who were often physically aggressive in elementary school were at risk for continuing violent and nonviolent forms of delinquency through adolescence (Broidy et al., 2003).

It is clear that helping children handle aggression can make a lasting difference in their lives. One of the best approaches for preventing problems with aggression later in life is to intervene early. For example, one study found that aggressive children whose teachers taught them conflict management strategies were diverted from a life path of aggression and violence (Aber, Brown, & Jones, 2003). Many aggressive students misread the intentions of others—assuming they “did it on purpose” when accidents happen. Sandra Graham (1996) has successfully experimented with approaches that help aggressive fifth- and sixth-grade boys become better judges of others’ intentions. Strategies include engaging in role-play, participating in group discussions of personal experiences, interpreting social cues from photographs, playing pantomime games, making videos, and writing endings to unfinished stories. The boys in the 12-session training group showed clear improvement in reading the intentions of others and responding with less aggression.

RELATIONAL AGGRESSION. Insults, gossip, exclusion, taunts—all are forms of relational aggression, sometimes called *social aggression* because the intent is to harm social connections. After second or third grade, girls tend to engage in relational aggression more than boys, possibly because as girls become aware of gender stereotypes, they push their overt aggression underground into verbal, not physical, attacks. Relational aggression can be even more damaging than overt physical aggression—to both the victim and the aggressor. Victims, like Stephanie in the chapter opening, often are devastated. Teachers and other students may view relational aggressors as even more problematic than physical aggressors (Ostrov & Godleski, 2010). As early as preschool, children need to learn how to negotiate social relations without resorting to any kind of aggression. Interviews with adolescents reveal how much they count on their teachers and other adults in the school to protect them (Garbarino & deLara, 2002). We will examine more specific classroom strategies, especially strategies for handling *bullying* and cyberbullying, in Chapter 13, *Managing Learning Environments*.

MEDIA, MODELING, AND AGGRESSION. Modeling plays an important role in the expression of aggression (Bandura, Ross, & Ross, 1963). One very real source of aggressive models is found in almost every home in America—television. Children ages 2 to 17 spend from 20 to 24 hours a week watching television—more time than any other activity except sleep (Hinckley, 2014). With all this viewing, the possible influence of television violence is a real concern because in the United States, 82% of TV programs have at least some violence. The rate for children’s programs is especially high—an average of 32 violent acts per hour, with cartoons being the worst. And in more than 70% of the violent scenes, the violence goes unpunished (Kirsh, 2005). Children will see about two gun-related incidents of violence for every hour of TV they watch (Common Sense Media, 2013a). Does watching violent TV increase aggression? A panel of experts assembled by the U.S. Surgeon General to study media and violence reached a strong

Cyber aggression Using email, Twitter, Facebook, or other social media to spread rumors, make threats, or otherwise terrorize peers.

GUIDELINES

Dealing with Aggression and Encouraging Cooperation

Present yourself as a nonaggressive model.

Examples

1. Do not use threats of aggression to win obedience.
2. When problems arise, model nonviolent conflict resolution strategies (see Chapter 13).

Ensure that your classroom has enough space and appropriate materials for every student.

Examples

1. Prevent overcrowding.
2. Make sure prized toys or resources are plentiful.
3. Remove or confiscate materials that encourage personal aggression, such as toy guns.
4. Avoid highly competitive activities and evaluations.

Make sure students do not profit from aggressive behaviors.

Examples

1. Comfort the victim of aggression, and ignore the aggressor.
2. Use reasonable punishment, especially with older students.

Teach directly about positive social behaviors.

Examples

1. Incorporate lessons on social ethics/morality through reading selections and discussions.
2. Discuss the effects of antisocial actions such as stealing, bullying, and spreading rumors.

3. Provide models and encouragement; role-play appropriate conflict resolution.

4. Develop self-esteem by building skills and knowledge.

5. Seek help for students who seem especially isolated and victimized.

Provide opportunities for learning tolerance and cooperation.

Examples

1. Emphasize the similarities among people rather than the differences.
2. Set up group projects that encourage cooperation.

Be knowledgeable about the video games your students are playing.

Examples

1. Play the games yourself or with a child to see what is actually happening.
2. Talk to students about the differences between what takes place in games and what happens in the real world.
3. Read reviews about the games to be informed.

See <https://www.commonsensemedia.org/violence-in-the-media#>

For more ideas, see the National Youth Violence Prevention Resource Center: safeyouth.gov/Resources/Prevention/Pages/PreventionHome.aspx and Common Sense Media <https://www.commonsensemedia.org/violence-in-the-media#>

and clear conclusion: “Research on violent television and films, video games, and music reveals unequivocal evidence that media violence increases the likelihood of aggressive and violent behavior in both immediate and long-term contexts” (C. A. Anderson et al., 2003, p. 81).

You can reduce the negative effects of TV violence by stressing three points with your students: (1) most people do not behave in the aggressive ways shown on television; (2) the violent acts on TV are not real, but are created by special effects and stunts; and (3) there are better ways to resolve conflicts, and most real people use those ways to solve their problems (Huesmann et al., 2003). Also, avoid using TV viewing as a reward or punishment because that makes television even more attractive to children. But television is not the only source of violent models. Students growing up in the inner cities see gang violence. Web posts, newspapers, and magazines are filled with stories of murders, rapes, and robberies. Many popular films are also filled with graphic depictions of violence, often performed by the “hero” who saves the day. And what about those video games?

VIDEO GAMES AND AGGRESSIVE BEHAVIOR. Researchers reviewed 130 reports based on over 130,000 participants from Western countries such as the United States, Australia, Germany, Italy, the Netherlands, Portugal, and the United Kingdom, as well as from Japan (C. A. Anderson et al., 2010). They found that playing violent video games is a causal factor for increased aggressive thoughts, feelings, and actions, along with

decreased feelings of empathy. Culture and gender had very little impact on how susceptible players were to the effects of these games. The effects were small, however, and clearer for younger children. Other researchers have questioned the connection between violent video games and actual violent acts in the real world (Charles, Baker, Hartman, Easton, & Kreuzberger, 2013; Ferguson, 2015a; Ferguson, 2015b; Ferguson et al., 2015). They argue that measures of violent behaviors in laboratory situations for the college student participants are not predictors of actual violent actions committed by children and adolescents in the real world.

This issue is far from resolved. Even so, an important question facing teachers, parents, and our whole society is what we should do to limit the risks to children. See the *Guidelines: Dealing with Aggression and Encouraging Cooperation* on the previous page (Anderman, Cupp, & Lane, 2009; T. A. Murdock & Anderman, 2006).

Reaching Every Student: Teacher Support

Because they are the main adults in students' lives for hours each week, teachers have many opportunities to play a significant role in students' personal and social development. For students facing emotional or interpersonal problems, teachers are sometimes the best source of help. When students have chaotic and unpredictable home lives, they need a caring, predictable structure in school. They need teachers who set clear limits, are consistent, enforce rules firmly but not punitively, respect students, and show genuine concern. Being liked and respected by teachers can offset the negative effects of peer rejection in middle school. And students who have few friends but are not rejected—simply ignored by other students—can remain well adjusted academically and socially when they are liked and supported by teachers (Bishop, Ladwig, & Berryman, 2014; McCormick & O'Connor, 2015).

As a teacher, you can be available to your students if they want to talk about their personal problems without requiring them to do so. One of my student teachers gave a boy in her class a journal entitled "Very Hard Thoughts" so that he could write about his parents' divorce. Sometimes he talked to her about the journal entries, but at other times, he just recorded his feelings. The student teacher was very careful to respect the boy's privacy about his writings.

ACADEMIC AND PERSONAL CARING. When researchers ask students to describe a "good teacher," three qualities are consistently at the center of their descriptions. Good teachers have positive interpersonal relationships—they care about their students. Second, good teachers keep the classroom organized and maintain authority without being rigid or "mean." Finally, good teachers are good motivators—they can make learning fun by being creative and innovative so students learn something. Authoritative teaching strategies, like authoritative approaches to parenting, appear to lead to positive relationships with students and to enhance motivation for learning (Noguera, 2005; Woolfolk Hoy & Weinstein, 2006). We will look at motivation in Chapter 12 and at management in Chapter 13, so for now let's focus on caring and teaching.

Research has documented the value and importance of positive relationships with teachers for students at every grade level (Allen et al., 2013; R. I. Chapman et al., 2013; Crosnoe et al., 2010; Hamre & Pianta, 2001; Shechtman & Yaman, 2012). Teachers' behaviors that communicate liking and respect, such as eye contact, relaxed body posture, and smiling, are associated with students' liking of teachers, interest in courses, and motivation to achieve (Woolfolk & Perry, 2015). For example, one of my doctoral graduates studied middle school mathematics classes and found that students' perceptions of their teachers' support and caring were related to the effort they invested in learning math (Sakiz, Pape, & Woolfolk Hoy, 2008). Tamera Murdock and Angela Miller (2003) found that eighth-grade students' perceptions that their teachers cared about them were significantly related to the students' academic motivation, even after taking into account the motivational influences of parents and peers. In high school, teacher sensitivity to the students' needs and perspectives predicts the students' performance on end-of-year standardized tests (Allen et al., 2013).

Students define caring in two ways. One is *academic caring*—setting high, but reasonable expectations and helping students reach those goals. The second is *personal caring*—being patient, respectful, humorous, willing to listen, interested in students' issues and personal problems. For students who are higher achieving, academic caring is especially important, but for students who are placed at risk and are often alienated from school, personal caring is critical (Cothran & Ennis, 2000; Woolfolk Hoy & Weinstein, 2006). In fact, in one study in a Texas high school, the Mexican and Mexican American students saw teacher caring as a prerequisite for their own caring about school; in other words, they needed to be *cared for* before they could *care about* school (Valenzuela, 1999). Unfortunately, in the same school, the mostly non-Latino teachers expected the students to care about school before they would invest their caring in the students. And for many teachers, caring about school meant behaving in more “middle-class” ways.

These contrasting student and teacher views can lead to a downward spiral of mistrust. Students withhold their cooperation until teachers “earn it” with their authentic caring. Teachers withhold caring until students “earn it” with respect for authority and cooperation. Marginalized students expect unfair treatment and behave defensively when they sense any unfairness. Teachers get tough and punish. Students feel justified about their mistrusting and become more guarded and defiant. Teachers feel justified in mistrusting and become more controlling and punitive, and on and on it goes (Woolfolk Hoy & Weinstein, 2006).

In another study that followed children from third through fifth grade, Pianta and his colleagues found that two factors helped children with lower skills in mathematics begin to close the achievement gap. The factors were higher-level (not just basic skills) instruction and positive relationships with teachers (Crosnoe, Morrison, Burchinal, Pianta, Keating, Friedman, & Clarke-Stewart, 2010). What is the lesson for teachers? Students need *both* appropriately challenging instruction and caring relationships. High expectations without caring can seem hopeless, punishing, and “mean” to students. Caring without high expectations can lead to feeling sorry for “underprivileged” students while excusing poor performance. Neither stance is helpful (Katz (1999). In short, caring means not giving up on students in addition to demonstrating and teaching kindness in the classroom (H. A. Davis, 2003; Milner, 2015).

Teachers and Child Abuse

Certainly, one critical way to care about students is to protect their welfare and intervene in cases of abuse. Although accurate information about the number of abused children in the United States is difficult to find because many cases go unreported, every year about 3,000,000 cases of abuse and neglect are reported and 900,000 are confirmed. That means a child is abused or neglected every 47 seconds (Children's Defense Fund, 2014). Of course, parents are not the only people who abuse children. Siblings, other relatives, and even teachers have been responsible for the physical and sexual abuse of children.

As part of your responsibilities as a teacher, you must alert your principal, school psychologist, or school social worker if you suspect abuse. In all 50 states, the District of Columbia, and the U.S. territories, the law requires certain professionals, usually including teachers, to report suspected cases of child abuse. The legal definition of *abuse* has been broadened in many states to include neglect and failure to provide proper care and supervision. Be sure that you understand the laws in your state or province on this important issue, as well as your own moral responsibility. At least four children die of abuse or neglect each day in the United States, in many cases because no one would “get involved” (Children's Defense Fund, 2014). Even children who survive abuse pay a great price. In school alone, physically abused children are more likely to be aggressive in the classroom and to have difficulty understanding social situations and recognizing emotions in others; these children also are retained in grades and referred for special education services more often than children who were not abused (Luke & Banerjee, 2013; Roeser et al., 2006). What should you look for as indicators of abuse? Table 3.2 on the next page lists possible indicators.

TABLE 3.2 • Indicators of Child Abuse

The following are some of the signs of abuse. Not every child with these signs is abused, but these indicators should be investigated. To learn about who must report child abuse, see childwelfare.gov/topics/systemwide/laws-policies/statutes/mandatory/.

	PHYSICAL INDICATORS	BEHAVIORAL INDICATORS
Physical Abuse	• Unexplained bruises and welts (in various stages of healing), marks in the shape of belt buckles or electrical cords, human bite marks, puncture marks, bald spots, regularly appearing after absences or weekends • Unexplained burns, especially cigarette burns, burns in the shape of irons, rope burns, or immersion-burns (sock-like or glove-like) • Unexplained fractures, lacerations, or abrasions in various stages of healing • Injuries attributed to the child being “clumsy” or “accident prone”	• Awkward movements, complains of soreness • Self-destructive • Withdrawn and aggressive—behavioral extremes • Uncomfortable with physical contact • Arrives at school early or stays late, as if afraid • Chronic runaway (adolescents) • Wears high-neck, long-sleeved clothing, not matching weather, to cover body • Frequent absences
Physical Neglect	• Abandonment • Unattended physical problems or medical needs • Constant fatigue, lack of energy • Little or no supervision • Often hungry, dressed inappropriately for weather, poor hygiene • Lice, distended stomach, emaciation	• Falls asleep in class • Steals food, begs from classmates • Reports that no caretaker is at home • Frequently absent or tardy, or stays as long as possible at school • Self-destructive • Trouble with the law
Sexual Abuse	• Difficulty walking or sitting • Pain or itching in genital area • Torn, stained, or bloodied underclothing • Bruises or bleeding in external genitalia • Venereal disease, especially in preteens • Frequent urinary or yeast infections • Pregnancy	• Doesn’t want to change for gym, PE • Withdrawn, chronic depression • Role reversal, overly concerned for siblings • Promiscuity, excessive seductiveness • Peer problems, lack of involvement • Massive weight change • Suicide attempts (especially adolescents) • Inappropriate sex play or premature understanding of sex, frequent masturbation, sexual play with dolls or stuffed animals • Sudden school difficulties

Society and Media

All of the students you will teach are growing up in a world of media, mobility, and machines. Today, 75% of children ages 0 to 8 live in homes with at least one mobile device—smartphone, iPad, iPod, laptop—many of these children have their own (Common Sense Media, 2013b). In 2015, 88% of adolescents ages 13 to 17 had access to a cell phone, and for 75% that phone was a smartphone. Many had computers, even from early ages.

FIGURE 3.4

TECHNOLOGY AND KEEPING IN TOUCH WITH FRIENDS

Daily Use of Social and Digital Communications by 13- to 17-year-olds. When do they study?

Source: Common Sense Media (2012). *Social Media, Social Life: How Teens View Their Digital Lives*. San Francisco: Common Sense Media, p. 9. Available at [socialmediasociallife-final-061812.pdf](https://www.common-sense-media.org/wp-content/uploads/2012/06/socialmediasociallife-final-061812.pdf)

Each year adolescents' use of technology increases (Common Sense Media, 2013b; Lenhart, 2015). Figure 3.4 shows the different technologies that 13 to 17-year-olds use daily.

One research project found that 13-year-olds check their phones on average 100 times a day for social media updates (Walsh, 2015). When do they have time for anything else? And these social media posts demand immediate attention. One high school sophomore told Sherry Turkle (2011) that within his circle of friends, texts had to be answered as soon as possible, within 10 minutes maximum. As he noted, "Texting is pressure" (p. 266). This pressure means that peers and even parents are always present—their messages demanding a response, even if the student is in class and must text in secret under the desk or with hands inside a backpack. What will it be like to teach students who send and receive over 100 text messages a day, and who can't focus on your class when a Pinterest posting appears? These are questions you will have to answer when you step into a classroom.

MyLab Education [Self-Check 3.2](#)

IDENTITY AND SELF-CONCEPT

In this section we look at the development of identity and sense of self. You will see patterns similar to those noted in Chapter 2 for cognitive development. Children's understandings of themselves are concrete at first. Early views of self and friends are based on immediate behaviors and appearances. Children assume that others share their feelings and perceptions. Their thinking about themselves and others is simple, segmented, and rule-bound, not flexible or integrated into organized systems. In time, children can think abstractly about internal processes—beliefs, intentions, values, and motivations. With these developments in thinking, children can incorporate more abstract qualities into their knowledge of self, others, and morality (Harter, 2003, 2006; Woolfolk & Perry, 2015).

In this section you will encounter the term *identity* along with several *self-* terms: *self-concept*, *self-esteem*, and *self-worth*. The distinctions among these terms are not always sharp; even psychologists disagree about what each term means (Roeser et al.,

2006). We start by examining *identity*. In general, identity is a broader concept than the *self*- terms. **Identity** includes people's general sense of themselves along with all their beliefs, emotions, values, commitments, and attitudes (Wigfield et al., 2006). Identity answers the question, "Who are you?" Your identity rests on two notions. First, you are different from all other people—there is no other person who is identical to you out there, now or ever. Second, you are the same individual over time, even if you change your appearance, beliefs, knowledge, location, friends, career—you get the idea (Baumeister, 2005). Like the child in Chapter 2 who used the concept of identity to know that even when water is poured from a short glass into a tall skinny glass it is the same amount, you know you are the same person, even when you go through many changes in life. We begin our consideration of identity with the framework of Erik Erikson.

Erikson: Stages of Psychosocial Development

Like Piaget, Erik Erikson (1902–1994) did not start his career as a psychologist. He skipped college, travelled around Europe, and ended up teaching in Vienna, where he studied psychoanalysis with Anna Freud, the daughter of Sigmund Freud. Soon after completing his training, he had to flee from the Nazis. He was denied citizenship in Denmark, so he moved to his second choice—New York City. Even though he had never attended college, on the basis of his groundbreaking work, he became a distinguished University Professor at Harvard. Later in his career he worked with the original Dr. Spock—Benjamin Spock, the widely read pediatrician whose books guided many Baby Boomers' parents, mine included (Green & Piel, 2010; P. H. Miller, 2016).

Erikson offered a basic framework for understanding the needs of young people in relation to the society in which they grow, learn, and later make their contributions. Erikson's **psychosocial** theory emphasizes the emergence of the self, the search for identity, the individual's relationships with others, and the role of culture throughout life.

Like Piaget, Erikson regarded development as a passage through an interdependent series of stages, each with its particular goals, concerns, accomplishments, and dangers, as shown in Table 3.3. At each stage, Erikson suggests that the individual faces a **developmental crisis**. Each crisis can be resolved by embracing an extreme position or by the healthier and more productive stance of finding a balance between the extreme responses. The way in which the individual resolves each crisis influences the resolution of future crises and has a lasting effect on that person's identity and view of society. We will look briefly at all eight stages in Erikson's theory—or, as he called them, the "eight ages of man."

THE PRESCHOOL YEARS: TRUST, AUTONOMY, AND INITIATIVE. Erikson identifies trust versus mistrust as the basic conflict of infancy. According to Erikson, the infant will develop a sense of trust if its needs for food and care are met with comforting regularity and responsiveness from caregivers. In this first year, infants are in Piaget's sensorimotor stage and are just beginning to learn that they are separate from the world around them. Thus infants must trust the aspects of their world that are separate and beyond their control (P. H. Miller, 2016; Posada et al., 2002). Having a secure attachment (described earlier in this chapter) helps young children develop trust and also learn when mistrust is appropriate—either extreme of complete trust or mistrust is dysfunctional.

Erikson's second stage, **autonomy versus shame and doubt**, marks the beginning of self-control and self-confidence as young children begin to assume responsibilities for self-care such as feeding, toileting, and dressing. During this period, parents must tread a fine line in being protective—but not overprotective. If parents do not reinforce their children's efforts to master basic motor and cognitive skills, children may begin to feel shame; they may learn to doubt their abilities to manage the world. Of course, some doubt is appropriate if the task is too difficult or dangerous—again the need for balance.

For Erikson, the next stage of **initiative versus guilt** "adds to autonomy the quality of undertaking, planning, and attacking a task for the sake of being active and on the move" (Erikson, 1963, p. 255). The challenge of this period is to maintain a balance between zest for activity and an understanding that not every impulse can be acted on. Again, adults

Connect and Extend to PRAXIS II®

Erikson's Psychosocial Theory of Development (I, A1, 2)

The school population spans four stages of Erikson's theory. Identify the major crisis of each of these stages. How can teachers support positive resolution of each of these stages? What are the implications for negative resolution of these crises?

Identity The complex answer to the question: "Who am I?"

Psychosocial Describing the relation of the individual's emotional needs to the social environment.

Developmental crisis A specific conflict whose resolution prepares the way for the next stage.

Autonomy Independence.

Initiative Willingness to begin new activities and explore new directions.

TABLE 3.3 • Erikson's Eight Stages of Psychosocial Development

STAGES	APPROXIMATE AGE	IMPORTANT EVENT	DESCRIPTION
1. Basic trust versus basic mistrust	Birth to 12–18 months	Feeding	The infant must form a first loving, trusting relationship with the caregiver or develop a sense of mistrust.
2. Autonomy versus shame/doubt	18 months to 3 years	Toilet training	The child's energies are directed toward the development of physical skills, including walking, grasping, controlling the sphincter. The child learns control but may develop shame and doubt if not handled well.
3. Initiative versus guilt	3 to 6 years	Independence	The child continues to become more assertive and to take more initiative but may be too forceful, which can lead to guilt feelings.
4. Industry versus inferiority	6 to 12 years	School	The child must deal with demands to learn new skills or risk a sense of inferiority, failure, and incompetence.
5. Identity versus role confusion	Adolescence	Peer relationships	The teenager must achieve identity in occupation, gender roles, politics, and religion.
6. Intimacy versus isolation	Young adulthood	Love relationships	The young adult must develop intimate relationships or suffer feelings of isolation.
7. Generativity versus stagnation	Middle adulthood	Parenting/Mentoring	Each adult must find some way to satisfy and support the next generation.
8. Ego integrity versus despair	Late adulthood	Reflection on and acceptance of one's life	The culmination is a sense of acceptance of oneself and a sense of fulfillment.

Source: Lefton, Lester A., *Psychology* (5th Ed.). © 1994. Reprinted by permission of Pearson Education, Inc. Upper Saddle River, NJ.

must tread a fine line, this time in providing supervision without interference. If children are not allowed to do things on their own, a sense of guilt may develop; they may come to believe that what they want to do is always “wrong.” The *Guidelines: Encouraging Initiative and Industry* on the next page suggest ways of encouraging initiative.

THE ELEMENTARY AND MIDDLE SCHOOL YEARS: INDUSTRY VERSUS INFERIORITY.

Let's set the stage for the next phase. Between the ages of 5 and 7, when most children start school, cognitive development is proceeding rapidly. Children can process more information faster, and their memory spans are increasing. They are moving from preoperational to concrete-operational thinking. As these internal changes progress, the children are spending hours every weekday in the new physical and social world of school. They must now reestablish Erikson's stages of psychosocial development in the unfamiliar school setting. They must learn to trust new adults, act autonomously in this more complex situation, and initiate actions in ways that fit the new rules of school—they are ready for the next stage.

GUIDELINES

Encouraging Initiative and Industry

Encourage children to make and to act on choices.

Examples

1. Have a free-choice time when children can select an activity or game.
2. As much as possible, avoid interrupting children who are very involved in what they are doing.
3. When children suggest an activity, try to follow their suggestions or incorporate their ideas into ongoing activities.
4. Offer positive choices: Instead of saying, "You can't have the cookies now," ask, "Would you like the cookies after lunch or after naptime?"

Make sure that each child has a chance to experience success.

Examples

1. When introducing a new game or skill, teach it in small steps.
2. Avoid competitive games when the range of abilities in the class is great.

Encourage make-believe with a wide variety of roles.

Examples

1. Have costumes and props that go along with stories the children enjoy. Encourage the children to act out the stories or make up new adventures for favorite characters.
2. Monitor the children's play to be sure no one monopolizes playing "teacher," "Mommy," "Daddy," or other heroes.

Be tolerant of accidents and mistakes, especially when children are attempting to do something on their own.

Examples

1. Use cups and pitchers that make it easy to pour and hard to spill.
2. Recognize the attempt, even if the product is unsatisfactory.

3. If mistakes are made, show students how to clean up, repair, or redo.
4. If a student consistently behaves in ways that are highly unusual or unacceptable, seek guidance from the school counselor or psychologist. The best time to help children deal with psychosocial problems is at an early age.

Make sure that students have opportunities to set and work toward realistic goals.

Examples

1. Begin with short assignments, then move on to longer ones. Monitor student progress by setting up progress checkpoints.
2. Teach students to set reasonable goals. Write down goals, and have students keep a journal of progress toward these goals.

Give students a chance to show their independence and responsibility.

Examples

1. Tolerate honest mistakes.
2. Delegate to students tasks such as watering class plants, collecting and distributing materials, monitoring the computer lab, grading homework, keeping records of forms returned, and so on.

Provide support to students who seem discouraged.

Examples

1. Use individual charts and contracts that show student progress.
2. Keep samples of earlier work so students can see how they have improved.
3. Have awards for most improved, most helpful, most hardworking.

The psychosocial challenge for the school years is what Erikson calls *industry versus inferiority*. Students are beginning to see the relationship between perseverance and the pleasure of a job completed. In modern societies, children must cope with more demanding academics and complex social relationships, all the time being compared to others and risking failure. Success in facing these new challenges will lead to a growing sense of competence. Difficulty can result in feelings of inferiority. Because schools tend to reflect middle-class values and norms, making the transition to school may be especially difficult for children who differ economically or culturally. The *Guidelines: Encouraging Initiative and Industry* give ideas that encourage industry.

After elementary school, in the transition to middle school, students confront an increased focus on grades and performance as well as more competition on all fronts—academic, social, and athletic. Just when they are eager to make decisions and assume more independence, students encounter more rules, required courses, and assignments. They change from a close connection with one teacher all year to more impersonal

Industry Eagerness to engage in productive work.

relations with numerous teachers in many different subjects across the year. They also go from being the most mature and highest status students in a small, familiar elementary school to being the “babies” in a large, impersonal middle school (T. B. Murdock, Hale, & Weber, 2001; Rudolph, Lambert, Clark, & Kurlakowsky, 2001). In this demanding context, they face the next challenge—*identity*.

ADOLESCENCE: THE SEARCH FOR IDENTITY. As students move into adolescence, they are developing capabilities for abstract thinking and understanding the perspectives of others. Even greater physical changes are taking place as the students approach puberty. So, with developing minds and bodies, young adolescents must confront the central issue of constructing an identity that will provide a firm basis for adulthood. The individual has been developing a sense of self since infancy. But adolescence marks the first time that a conscious effort is made to answer the now-pressing question: “Who am I?” The conflict defining this stage is *identity* versus *role confusion*. *Identity* refers to the organization of the individual’s drives, abilities, beliefs, and history into a consistent image of self. It involves deliberate choices and decisions, particularly about work, values, ideology, and commitments to people and ideas (P. H. Miller, 2016). If adolescents fail to integrate all these aspects and choices, or if they feel unable to choose at all, *role confusion* threatens.

STOP & THINK Have you decided on your career? What alternatives did you consider? Who or what was influential in shaping your decision? •

James Marcia (1967, 1994, 2007; Kroger & Marcia, 2013) expanded on Erikson’s theory of identity formation by focusing on two essential processes: exploration and commitment. **Exploration** refers to the process by which adolescents consider and try out alternative beliefs, values, and behaviors. **Commitment** refers to individuals’ choices concerning political and religious beliefs, for example, usually as a consequence of exploring the options. Then, Marcia identified four categories or *identity status* that arise from four patterns of exploration and commitment.

The first, **identity achievement**, means that after *exploring* the realistic options, the individual has made choices and is *committed* to pursuing them. It appears that few students achieve this status by the end of high school; students who attend college may take even longer to decide. About 80% of students change their majors at least once (just ask my mom—she is sure I had 5 different majors before I settled on psychology). And identity, once achieved, may not be unchanging for everyone (Arnett, 2015; Kroger et al., 2010; Kroger & Marcia, 2013).

Adolescents in the midst of struggling with choices are experiencing what Erikson called a **moratorium**. Erikson used the term *moratorium* to describe exploration with a delay in commitment to personal and occupational choices. This delay is very common, and probably healthy, for modern adolescents. Erikson believed that adolescents in complex societies have an identity crisis during moratorium. Today, the period is no longer referred to as a *crisis* because, for most people, the experience is a gradual exploration rather than a traumatic upheaval (Kroger & Marcia, 2013; Wigfield, Byrnes, & Eccles, 2006). Both identity-achieved and moratorium statuses are considered healthy.

Identity foreclosure is commitment without exploration. Foreclosed adolescents have not experimented with different identities or explored a range of options, but simply have committed themselves to the goals, values, and lifestyles of others—usually their parents, but sometimes cults or extremist groups. Foreclosed adolescents tend to be rigid, intolerant, dogmatic, and defensive.

Identity diffusion occurs when individuals do not explore any options or commit to any actions. They reach no conclusions about who they are or what they want to do with their lives. Adolescents experiencing identity diffusion may be apathetic and withdrawn, with little hope for the future, or they may be openly rebellious. These adolescents often go along with the crowd, so they are more likely to abuse drugs (Archer & Waterman, 1990; Kroger, 2000).

Exploration In Marcia’s theory of identity statuses, the process by which adolescents consider and try out alternative beliefs, values, and behaviors in an effort to determine which will give them the most satisfaction.

Commitment In Marcia’s theory of identity statuses, individuals’ choices concerning political and religious beliefs, for example, usually as a consequence of exploring the options.

Identity achievement Strong sense of commitment to life choices after free consideration of alternatives.

Moratorium Identity crisis; suspension of choices because of struggle.

Identity foreclosure Acceptance of parental life choices without consideration of options.

Identity diffusion Uncenteredness; confusion about who one is and what one wants.

IDENTITY AND TECHNOLOGY. Some scholars of technology have speculated that establishing a separate identity is complicated for adolescents today because they are constantly connected to others. Parents often give a cell phone to their children somewhere between the ages of 7 and 10, or even earlier, with the specific requirement that the children always answer a call from the parent. Sherry Turkle (2011) calls this happy recipient of a new cell phone a “tethered child.” But the price paid for having a cell phone is that these tethered children never navigate social and physical landscapes completely alone—parents and friends are only a speed dial away. So the chance to solve problems and handle situations alone, the basis for achieving identity and mature judgment, is lost. A friend of mine is a physician at a university health center. She describes undergraduate patients who respond to her question, “What are your health concerns today?” with the answer, “My mom is on the phone—she’ll tell you” and then the college student hands a cell phone to the doctor. Constant connectivity complicates achieving a separate identity and autonomy, not to mention doctor–patient confidentiality.

Connectivity also “offers new possibilities for experimenting with identity, particularly in adolescence, the sense of a free space, what Eric Erikson called the *moratorium*” (Turkle, 2011, p. 152). On Second Life, The Sims Online, dating simulations, or other life-simulation sites, adolescents can create whole new identities and keep multiple personalities “alive.” Some people even talk about their “life mix,” a mash up of what they live online and what they live in real life. For some adolescents, the boundaries may be unclear and easily crossed. Is the profile adolescents create on Facebook the “real” person, or as one high school senior described, the identity that you “mold” to present to the world? For connected and tethered adolescents today, Elkind’s (1985) imaginary audience (discussed in Chapter 2) is now a real, online audience. The consequences are not all positive, as another senior agonized: “You have to know that everything you put up will be perused very carefully. And that makes it necessary for you to obsess over what you do put up and how you portray yourself. . . .” (Turkle, 2011, p. 184).

Schools that give adolescents guidance in the safe uses of social media, experiences with community service, real-world work, internships, and mentoring help to foster identity formation. See the *Guidelines: Supporting Identity Formation*.

BEYOND THE SCHOOL YEARS. The crises of Erikson’s stages of adulthood all involve the quality of human relations. *Intimacy versus isolation* refers to a willingness to relate to another person on a deep level, to have a relationship based on more than mutual need. Someone who has not achieved a sufficiently strong sense of identity tends to fear being overwhelmed or swallowed up by another person and may retreat into isolation. *Generativity versus stagnation* extends the ability to care for another person and involves concern and guidance for both the next generation and future generations. Productivity and creativity are essential features. Achieving *integrity versus despair* means consolidating your sense of self and fully accepting its unique and now unalterable history (Hearn et al., 2012).

Erikson’s work helped start the life-span development approach, and his theories have been especially useful in understanding adolescence and developing concepts of self. But his work has been criticized because his descriptions are quite general and there really is no way to test his principles. He describes *what* changes without explaining *how* (P. H. Miller, 2016). Feminists have criticized his notion that identity precedes intimacy, because their research indicates that for women, identity achievement is fused with achieving intimacy (Horst, 2011). And, as you will see next, recent research has focused on identity issues not fully explored by Erikson—racial and ethnic identity.

Racial and Ethnic Identity

As early as 1903, W. E. B. Du Bois wrote about the “double consciousness” of African Americans. In essence, African Americans, like other ethnic or racial groups, are conscious of their racial or ethnic identity as they negotiate being members of the larger culture as well. For example, college students from underrepresented groups must develop a bicultural identity, staying connected to their own cultures as they also form

Intimacy Forming close, enduring relationships with others.

Generativity Sense of concern for future generations.

Integrity Sense of self-acceptance and fulfillment.

GUIDELINES

Supporting Identity Formation

Give students many models for career choices and other adult roles.

Examples

1. Point out models from literature and history. Have a calendar with the birthdays of eminent women, minority leaders, or people who made a little-known contribution to the subject you are teaching. Briefly discuss the person's accomplishments on his or her birthday.
2. Invite guest speakers to describe how and why they chose their professions. Make sure all kinds of work and workers are represented.

Help students find resources for working out personal problems.

Examples

1. Encourage them to talk to school counselors.
2. Discuss potential outside services.

Be tolerant of teenage fads as long as they don't offend others or interfere with learning.

Examples

1. Discuss the fads of earlier eras (neon hair, powdered wigs, love beads).
2. Don't impose strict dress or hair codes.

Give students realistic feedback about their work and support for improving. Adolescents may need many "second chances."

Examples

1. When students misbehave or perform poorly, make sure they understand the consequences of their behavior—the effects on themselves and others.
2. Give students model answers or show them other students' completed projects from previous years so they can compare their work to good examples.
3. Never use a student's work as a "bad" example. Create negative examples from multiple sources including mistakes you have made.
4. Because students are "trying on" roles, keep the roles separate from the person. Criticize the behavior without criticizing the student.

Caution students about the dangers of crafting identities online.

Examples

1. Discuss how colleges and employers check Facebook profiles of applicants.
2. Explore possible ways of maintaining personal safety when online.

identities as college students, chemistry majors, artists, or whatever other roles their studies require. In this process, friends and families become "identity agents" who provide links to home culture and support the students as they negotiate their identities in often White-dominated fields (Rodgers, 2016). Ethnic identity has been called a "master status," one that trumps all other identity concerns when judging the self (Charmaraman & Grossman, 2010; M. Herman, 2004).

Some psychologists have used Marcia's identity statuses to understand the process of forming an ethnic identity. Children may begin with an unexamined ethnic identity, either because they have not explored at all (diffusion) or because they have accepted the identity encouraged by others (foreclosure). Many European American adolescents could fit into the unexamined category. A period of ethnic identity exploration (moratorium) might be followed by a resolution of the conflict (identity achieved).

MULTIDIMENSIONAL AND FLEXIBLE ETHNIC IDENTITIES. Ethnic identity in the United States is a complex concept for all of us. But for many Hispanic students, identity also is multidimensional. For example, in a 2012 Pew Research Center survey, 51% of Hispanic adults identified more with the country or region of their ancestors (Cuba, Mexico, the Dominican Republic, the Caribbean, etc.) than with a general notion of Hispanic or Latino. Only 24% used the terms "Hispanic" or "Latino" to describe themselves and 21% used the term "American" as their identity. Just over two-thirds of the respondents in this survey believed that Hispanics in the U.S. have many different cultures. Most of the rest felt that Hispanics share a common culture. In spite of these differences, most respondents in the survey believed it was important to learn English, but also essential

for future generations to retain their Spanish language. Other Pew surveys (2015, López, & Gonzalez-Barrera, 2016) have found that over two-thirds of respondents described their Hispanic background as one aspect of their racial identity; many with Caribbean roots consider themselves Afro-Latino or Afro-Caribbean.

Other ethnic and cultural groups respond in similar ways. Adolescents in immigrant families find creative and flexible ways to describe their identities, depending on the situation. For example, sometimes they identify more strongly with their Chinese, Japanese, Pilipino, Vietnamese, or Moroccan heritage but in certain situations they identify with their new country. So these students may be navigating multiple cultures and identities (Fuligni & Tsai, 2015). Perhaps the best advice I can offer is to try to understand that many of your students will be constructing complex identities that allow them to move in and out of several cultures and languages. Get to know the individual students and respect their growing identities.

BLACK RACIAL IDENTITY: OUTCOME AND PROCESS. William Cross (1991; Cross & Cross, 2007; Cross, Grant, & Ana, 2012) devised a framework that specifically addresses African American racial identity and consciousness, that is, the process of becoming Black. The process he calls **nigrescence** has five stages:

- *Pre-encounter:* At this stage, Cross says that an African American's attitude may range from ignoring race to feeling neutral about race, to actually being anti-Black. African Americans at this stage may adopt certain beliefs of White Americans, including the tendency to see "Whiteness" as superior. Some level of self-hate is a possible consequence. At the pre-encounter stage, people value other aspects of their identity, such as religion, profession, or social status.
- *Encounter:* This stage is often triggered by encounters with overt, covert, or institutional racism. For instance, when an African American is followed around in an upscale store, is assaulted by police, or sees news reports about such assaults, then his or her eyes are opened to the reality that race matters in society. The African American becomes attuned to his or her Blackness.
- *Immersion/Emersion:* Cross sees this as a transition—an in-between state that may cause people to be anxious about "becoming the 'right kind' of Black person" (Cross, 1991, p. 202). In response to encounters with discrimination, the individuals fill their lives with symbols of Blackness; they buy books about Black experiences and socialize mainly with other African Americans, for example. They are eager to understand their racial heritage more deeply.
- *Internalization:* Individuals are firmly connected to and secure in their sense of racial identity. They don't worry about what friends or outsiders think—they are confident in their own standards of Blackness.
- *Internalization-Commitment:* This stage is very closely connected with internalization. The main difference is a person's continued interest in and commitment to Black affairs. Such individuals chart their lives to connect to their Black racial identity; for example, a painter dedicates his life to painting Black images or a researcher dedicates her life to studying African American educational experiences.

The nigrescence model does not necessarily fit every Black person in America. For example, the stages may not be appropriate for the identity development of first-generation U.S. born African students or for students with both a Latino and a Black heritage such as some Dominican-Americans (DeWalt, 2013). And determining a racial identity may be even more complicated for biracial or multiracial adolescents. The parent they live with, the make-up of their neighborhood, their appearance, and experiences of discrimination or support can influence these adolescents' decisions about racial identity. Some psychologists think that these challenges help multiracial youth develop stronger and more complex identities, but other researchers argue that the challenges present an extra burden in an already-tough process (M. Herman, 2004; Ritchey, 2015). Perhaps the outcome depends in part on the support adolescents receive in facing the challenges.

Nigrescence The process of developing a Black identity.

RACIAL AND ETHNIC PRIDE. No matter what your identity outcome is, having strong positive feelings about your own ethnic group seems to be important for good mental health as well as engagement and success in school (J. L. Cook & Cook, 2014; Steinberg, 2005). In fact, Amy Marks and her colleagues (Marks, Patton, & Coll, 2011) determined that bicultural adolescents who form strong, positive multiethnic identities have higher self-esteem, fewer mental health problems, and higher academic achievement than peers with a single ethnic identity or an undeveloped multiethnic identity. For all students, **racial and ethnic pride** in family and community is part of the foundation of a stable identity. In one study, researchers found that African American preschool students whose homes were rich with African American traditions had more factual knowledge and better problem-solving skills than students whose homes lacked rich cultural resources. Parents who encouraged their children to be proud of their heritage reported fewer behavior problems with their children than parents who did not encourage racial pride (Caughy, O'Campo, Randolph, & Nickerson, 2002). In other research, positive racial identity was found to be related to higher self-esteem and fewer emotional problems for both African American and White adolescents (DuBois, Burk-Braxton, Swenson, Tevendale, & Hardesty, 2002).

Each of us has an ethnic heritage. Janet Helms (1995, 2014) has written about stages in White identity development. H. Richard Milner (2003, 2015) has pointed to the importance of racial identity development and awareness, especially in teaching. When majority adolescents are knowledgeable and secure about their own heritage, they are also more respectful of the heritage of others. Thus, exploring the racial and ethnic roots of all students should foster both pride in self and acceptance of others (Rotherham-Borus, 1994).

In the next sections we move from overarching considerations of identity to more specific conceptions of self. In educational psychology, much research is focused on self-concept and self-esteem.

Self-Concept

The term *self-concept* is part of our everyday conversations. We talk about people who have a “low” self-concept or individuals whose self-concept is not “strong,” as if self-concept were the oil level in a car or the fitness of your abdominal muscles. These actually are misuses of the term. In psychology, **self-concept** generally refers to our mental picture of who we are. It is our attempt to explain ourselves to ourselves, to build a scheme (in Piaget's terms) that organizes our impressions, attitudes, and beliefs about ourselves (Harter, 2006; Pajares & Schunk, 2001). But this model or scheme is not permanent, unified, or unchanging. Our self-perceptions can vary from situation to situation and from one phase of our lives to another.

THE STRUCTURE OF SELF-CONCEPT. Self-concept is multidimensional, as shown in Figure 3.5 on the next page. At the top of the hierarchy is general self-concept. This general self-concept is also called *global self-esteem* in the hierarchical model and can be defined as individuals' “self-perceptions of themselves as effective, capable individuals who have self-confidence and self-respect and are proud and satisfied with the way they are” (Marsh, Trautwein, Lüdtke, Köller, & Baumert, 2006, p. 455). At the next level are more specific self-perceptions, including *academic* and *nonacademic* self-concepts, and these self-concepts are made up of even more specific concepts such as self-concepts in math and languages or appearance and popularity. Herbert Marsh and his colleagues have identified up to 16 different self-concepts in *academic* and *nonacademic* areas, as you can see in Figure 3.5. These specific self-concepts are not highly correlated. For example, even though school *achievement* in verbal and math subjects is consistently correlated, verbal and math *self-concepts* are not correlated at all (Marsh, Xu, and Martin, 2012).

For academic subjects, self-concepts include both perceptions of competence (I am good in science) and affect or attitudes (I like science) (Arens, Yeung, Crave,

MyLab Education
Podcast 3.1

Textbook author Anita Woolfolk describes the findings on self-concept, self-esteem, and self-efficacy and explains the differences among these important concepts in educational psychology. Should teachers focus on building self-esteem? Is there a better approach to helping students build a positive sense of self?

Racial and ethnic pride

A positive self-concept about one's racial or ethnic heritage.

Self-concept Individuals' knowledge and beliefs about themselves—their ideas, feelings, attitudes, and expectations.

FIGURE 3.5

A HIERARCHIAL MODEL OF SELF-CONCEPT

Source: Based on ideas from Marsh, H. W. (1990). The structure of academic self-concept: The Marsh/Shavelson Model. *Journal of Educational Psychology* 82, 623-636. Marsh, H. W., Xu, M., & Martin, A. J. (2012). Self-concept: A synergy of theory, method, and application. In K. R. Harris, S. Graham, & T. C. Urdan (Eds.) *APA educational psychology handbook, Vol. 1: Theories, constructs, and critical issues* (pp. 427-458). Washington, DC: American Psychological Association. Brunner, M., Keller, U., Dierendonck, C., Reichert, M., Ugen, S., Fischbach, A., & Martin, R. (2010). The Structure of academic self-concepts revisited: The nested Marsh/Shavelson Model. *Journal of Educational Psychology*, 102, 964-981.

& Hasselhorn, 2011). For adolescents, both their overall *academic self-concept* (how quickly they learn or how well they do in school in general) and their *subject-specific self-concept* (how good they think they are in math, their attitudes toward math) may influence their decisions and motivation. For example, your educational aspirations and goals (e.g., deciding to attend college) are driven by your general academic self-concept. But the major you chose in college is influenced by your subject-specific academic self-concepts (Brunner et al., 2010).

HOW SELF-CONCEPT DEVELOPS. The self-concept evolves through constant self-evaluation in different situations and using different frames of reference. Children and adolescents are continually asking themselves, in effect, “How am I doing?” To answer, they gauge the verbal and nonverbal reactions of significant people—parents and other family members in the early years, and friends, schoolmates, and teachers later (Harter, 2006; Marsh, Xu, & Martin, 2012). These self-evaluations contribute to a person’s self-concept in any given domain and also to general self-concept/global self-esteem, which is discussed in a later section.

Younger children tend to have positive and optimistic self-concepts. They don’t yet compare themselves to peers; they just compare their current skill level to what they could do earlier in their lives and see improvement. In some ways this confidence protects them from disappointment and maintains persistence—a good thing for developing children (Harter, 2006).

For older students, both self and other comparisons and reference groups shape self-concepts, at least in Western cultures. Students’ self-concepts in math are shaped by *internal comparisons*—how their math performance compares to their performance in history, for example. They also make *external comparisons* to other students’ math performance. Generally speaking, students who are strong in math in an average class feel better about their math skills than do students of equal ability in a high-achieving class.

Marsh and his colleagues call this the BFLPE, short for the “Big-Fish-Little-Pond-Effect” (Marsh, Abduljabbar, et al., 2015; Marsh, Kuyper, et al., 2014; Salchegger, 2016). For example, Marsh and his colleagues (2014) studied over 15,000 ninth-grade students from 651 classes in 95 Dutch schools. The researchers found strong evidence that students’ academic self-concepts are largely determined by comparisons to other students in their own classrooms, not comparisons to students in other classes or other schools. Participation in a gifted and talented program seems to have a “Little-Fish-in-Big-Pond Effect”: Students who participate in gifted programs, compared to similar students who remain in general education classes, tend to show declines in academic self-concepts over time, but no changes in nonacademic self-concepts (Marsh & Craven, 2002; Preckel, Goetz, & Frenzel, 2010). Even though the BFLPE seems widespread, there is some indication that the effect is larger when students are tracked early, formally, and permanently into different types of schools, and smaller when students are grouped into schools informally based on neighborhoods (Salchegger, 2016).

Before we move on to look at self-concept and achievement, an important caveat is in order. The development of self-concept does not follow the same path in every culture. Most Western and European parents want their children to develop a strong sense of self and a spirit of independence, but many Asian parents want their children to develop a strong sense of interdependence in relation to their family, community, and culture (Peterson, Cobas, Bush, Supple, & Wilson, 2004). And not all subcultures within Western societies emphasize independence to the same extent. For example, many Latino children are taught that their personal identities are interdependent and inseparable from the identity of their families (Parke & Buriel, 2006).

SELF-CONCEPT AND ACHIEVEMENT. Many psychologists consider self-concept to be the foundation of both social and emotional development. Research has linked self-concept to a wide range of accomplishments—from performance in competitive sports to job satisfaction to achievement in school (Byrne, 2002; Goetz, Cronjaeger, Frenzel, Ludtke, & Hall, 2010; Marsh & O’Mara, 2008; Möller & Pohlmann, 2010). Some evidence for the link between self-concept and school achievement shows that performance in academic subjects is correlated with specific self-concepts in those areas, but not with social or physical self-concepts. For example, in one study, math self-concept correlated .77 with math test scores, .59 with grades, and .51 with coursework selection (Marsh et al., 2006; O’Mara, Marsh, Craven, & Debus, 2006). That last correlation of math self-concept with course selection points to an important way self-concept affects learning in school. Think back to high school. When you had a chance to choose courses, did you pick your worst subjects—those where you felt least capable? Probably not. The courses selected in high school put students on a path toward the future, so self-concepts about particular academic subjects can be life-changing influences.

Unfortunately, heavy emphasis on grade point averages (GPAs) for admission to some colleges can affect course choice as well, especially if students avoid classes to protect their GPAs because they see themselves as “no good” in math, science, world languages, or other challenging classes. Of course, we know from Chapter 1 that correlation is not cause; higher self-concept probably can encourage higher achievement, but high achievement likely also leads to higher self-concept, so the causes work in both directions (Marsh, Xu, & Martin, 2012).

Sex Differences in Self-Concept of Academic Competence

Do girls and boys differ in their self-concepts? A study followed 761 middle-class, primarily European American students from first grade through high school (Jacobs, Lanza, Osgood, Eccles, & Wigfield, 2002). It is difficult to get longitudinal data, so this is a valuable study. In first grade, girls and boys had comparable perceptions of their own abilities in language arts, but boys felt significantly more competent in math and sports. By high school, math competence beliefs were about the same for boys and girls. In sports, competence ratings for both boys and girls dropped, but boys

remained significantly more confident in their competence in sports throughout the entire 12 years.

Other studies have also found that girls tend to see themselves as more able than boys in reading and close friendships; boys are more confident about their abilities in math and athletics. Of course, some of these differences in self-confidence may reflect actual differences in achievement; girls tend to be better readers than boys, for example. As we have seen, many self-beliefs are reciprocally related to achievement—each affects the other (Eccles, Wigfield, & Schiefele, 1998; Marsh, Xu, & Martin, 2012). For most ethnic groups (except African Americans), boys are more confident than girls about their abilities in math and science. Unfortunately, there are no long-term studies of other ethnic groups, so these patterns may be limited to European Americans.

Because self-concept in a particular subject can affect course selection, teachers must be careful that their students do not avoid courses and subjects just because they don't feel confident. Later career paths can be closed if students avoid courses that are the gateways to those paths. Because self-concept and achievement probably affect each other, it makes sense to focus on both self-concept and performance enhancement:

In summary, whereas the optimal way to improve self-concept over the short-term is to focus interventions directly on self-concept enhancement, interventions that combine direct self-concept enhancement in concert with performance enhancement, coupled with appropriate feedback and praise, are likely to be advantageous when the goals of the intervention are to improve both self-concept and performance. (Marsh et al., 2006, p. 198).

Self-Esteem

STOP & THINK How strongly do you agree or disagree with the following statements?

- On the whole, I am satisfied with myself.
- I feel that I have a number of good qualities.
- I wish I could have more respect for myself.
- At times, I think that I am no good at all.
- I certainly feel useless at times.
- I take a positive attitude toward myself.

These *Stop & Think* questions are taken from a widely used measure of self-esteem (Hagborg, 1993; Rosenberg, 1979). •

Connect and Extend to PRAXIS II®

Self-Esteem (I, A2)

Understand the bidirectional effects of school life and self-esteem on each other. What can teachers do to enhance students' self-esteem?

Global self-esteem, at the top of the hierarchical model of self-concept, is an overall judgment of self-worth that includes feeling proud or ashamed of yourself as a person. Thus **self-esteem** is the *evaluative* dimension of self-concept. If people judge themselves positively—if they “like what they see”—we say that they have high self-esteem (Schunk et al., 2014). Can you see the judgments of self-worth in the *Stop & Think* questions? The questions are pretty general; no specific areas such as academics or appearance are targeted. Self-esteem is influenced by whether the culture around you values your particular characteristics and capabilities (Bandura, 1997; Schunk et al., 2014). Nearly 130 years ago, William James (1890) suggested that self-esteem is determined by how successful we are in accomplishing tasks or reaching goals we value. If a skill or accomplishment is not important, incompetence in that area doesn't threaten self-esteem.

Do schools affect self-esteem: Is school important? As you can see from the *Point/Counterpoint*, the school's role in student self-esteem has been hotly debated.

Self-esteem The value each of us places on our own characteristics, abilities, and behaviors.

MyLab Education **Self-Check 3.3**

POINT/COUNTERPOINT: What Should Schools Do to Encourage Students' Self-Esteem?

The attempts to improve students' self-esteem have taken three main forms: personal development activities such as sensitivity training; self-esteem programs where the curriculum focuses directly on improving self-esteem; and structural changes in schools that place greater emphasis on cooperation, student participation, community involvement, and ethnic pride. Are these efforts valuable?

POINT ► The self-esteem movement has big problems.

Some people have accused schools of developing programs where the main objective is "to dole out a huge heaping of praise, regardless of actual accomplishments" (Slater, 2002, p. 45). Frank Pajares and Dale Schunk (2002) point to another problem. "[W]hen what is communicated to children from an early age is that nothing matters quite as much as how they feel or how confident they should be, one can rest assured that the world will sooner or later teach a lesson in humility that may not easily be learned. An obsession with one's sense of self is responsible for an alarming increase in depression and other mental difficulties" (p. 16). In addition, sensitivity training and self-esteem courses assume that we encourage self-esteem by changing the individual's beliefs, making the young person work harder against the odds. But what if the student's environment is truly unsafe, debilitating, and unsupportive? Some people have overcome tremendous problems, but to expect everyone to do so all the time can become "blaming the victim," saying your problems are your fault because you have low self-esteem (Beane, 1991).

Worse yet, some psychologists are now contending that low self-esteem is not a problem, whereas high self-esteem may be. For example, people with high self-esteem are more willing to inflict pain and punishment on others (Baumeister, Campbell, Krueger, & Vohs, 2003; Slater, 2002). In addition, research consistently shows that improved self-esteem has no impact on achievement in school (Baumeister, 2005). For example, in a large study of adolescents, global self-esteem did not correlate with any of the 9 academic outcomes measured (Marsh et al., 2006). And when people set self-esteem as a main goal, they may pursue that goal in ways that are harmful over the long run. They may avoid constructive criticisms or challenging tasks (Crocker & Park, 2004). Psychologist Lauren Slater (2002), in her article "The Trouble with Self-Esteem," suggests that we rethink self-esteem and move toward honest self-appraisal that will lead to self-control. She suggests, "Maybe self-control should replace self-esteem as a primary peg to reach for" (p. 47).

COUNTERPOINT ► The self-esteem movement has promise.

Beyond the "feel-good psychology" of some aspects of the self-esteem movement is a basic truth: Self-esteem is a fundamental right of all humans. When self-esteem increases, we generally feel happier, whereas a decrease in self-esteem makes us feel unhappy. Higher self-esteem is associated with increased initiative, better coping with stress and trauma, and the ability to maintain a more stable mood as well (Baumeister, 2005). We deserve to respect ourselves, and neither the society nor its schools should undermine that respect. Remember the Girls Project described earlier, which reminds young girls that their value, and their self-esteem, should be based on their character, skills, and attributes—not appearance. If we view self-esteem accurately as a product of our thinking and our actions—our values, ideas, and beliefs as well as our interactions with others—then we see a significant role for the school. Practices that allow authentic participation, cooperation, problem solving, and accomplishment should replace policies that damage self-esteem, such as tracking and competitive grading.

Erik Erikson (1980) warned years ago: "Children cannot be fooled by empty praise and condescending encouragement. They may have to accept artificial bolstering of their self-esteem in lieu of something better. . . ." Erikson explained that a strong and positive sense of self comes only from "wholehearted and consistent recognition of real accomplishment, that is, achievement that has meaning in their culture" (p. 95).

Beware of Either/Or. Teachers' feedback, grading practices, evaluations, and communication of caring for students can make a difference in how students feel about their abilities in particular subjects. But the greatest increases in self-esteem come when students grow more competent in areas they value—including the social areas that become so important in adolescence. So, a teacher's greatest challenge is to help students achieve important understandings and skills (Osborne & Jones, 2011). Another possibility is to change the focus from self-esteem to more specific self-concepts, because self-concepts in specific areas such as math are related to learning in math (Marsh et al., 2015).

UNDERSTANDING OTHERS AND MORAL DEVELOPMENT

As we seek our own identity and form conceptions of ourselves, we are also learning about right and wrong. One aspect of moral development is understanding other people. How do we learn to interpret what others are thinking and feeling?

Theory of Mind and Intention

By the time they are 2 or 3 years old, children are beginning to develop a **theory of mind**, an understanding that other people are people too, with their own minds, thoughts, feelings, beliefs, desires, and perceptions (Berger, 2015; Carlson, Koenig, & Harms, 2013; S. A. Miller, 2009). Children need a theory of mind to make sense of other people's behavior. Why is Sarah crying? Does she feel sad because no one will play with her? Children also need a theory of mind to understand that beliefs can differ from reality and that people can have different views. And they need a theory of mind to devise plausible lies—they have to understand what other people might believe. As you will see in Chapter 4, one explanation for autism is that children with this condition lack a theory of mind to help them understand either their own or other people's emotions and behaviors.

Around the age of 2, children have a sense of intention, at least of their own intentions. They will announce, "I wanna peanut butter sandwich." As children develop a theory of mind, they also can understand that other people have intentions of their own. Older preschoolers who get along well with their peers can separate intentional from unintentional actions and react accordingly. For example, they will not get angry when another child accidentally knocks over their block tower. But aggressive children have more trouble assessing intention. They are likely to attack anyone who topples their tower, even accidentally (Dodge & Pettit, 2003). As children mature, they are more able to assess and consider the intentions of others.

With a developing theory of mind, children are increasingly able to understand that other people have different feelings and experiences and therefore may have a different viewpoint or perspective. This **perspective-taking ability** develops over time until it is quite sophisticated in adults. Being able to understand how others might think and feel is important in fostering cooperation and moral development, reducing prejudice, resolving conflicts, and encouraging positive social behaviors in general (Gehlbach, 2004). Some coaching in perspective taking from the teacher ("How would you feel if . . . ?" "Why do you think Charice . . . ?") might help if children mistreat peers and the mistreatment is not part of a deeper emotional or behavioral disorder (Woolfolk & Perry, 2015).

Moral Development

Along with a more advanced theory of mind and an understanding of intention, children also are developing a sense of right and wrong. Until recently, theory and research about moral development focused on children's **moral reasoning**, their thinking about right and wrong. Lately, some new perspectives building on insights from social and evolutionary psychology and neuroscience suggest there is more to morality than thinking (Haidt, 2013; Messina & Surprenant, 2015), as you will see later in this section. First, let's look at the most famous conception of moral development based on reasoning—Kohlberg's theory.

KOHLBERG'S THEORIES OF MORAL DEVELOPMENT. For years, Lawrence Kohlberg's (1963, 1975, 1981) theory of moral development, which was based in part on Piaget's ideas, dominated psychology and education.

PUT YOURSELF IN HIS PLACE A man's wife is dying. There is one drug that could save her, but it is very expensive, and the druggist who invented it will not sell it at a price low enough for the man to buy it. Finally, the man becomes desperate and considers stealing the drug for his wife. What should he do, and why? •

Kohlberg evaluated the moral reasoning of both children and adults by presenting them with **moral dilemmas**, or hypothetical situations like the one in *Stop & Think* in which people must make difficult decisions and give their reasons.

Theory of mind An understanding that other people are people too, with their own minds, thoughts, feelings, beliefs, desires, and perceptions.

Perspective-taking ability Understanding that others have different feelings and experiences.

Moral reasoning The thinking process involved in judgments about questions of right and wrong.

Moral dilemma Situations in which no choice is clearly and indisputably right.

Based on their reasoning, Kohlberg proposed a detailed sequence of six stages of moral reasoning, or judgments about right and wrong:

Preconventional Level: Judgment Is Based Solely on a Person's Own Needs and Perceptions

- Stage 1: *Obedience Orientation*—Obey rules to avoid punishments and bad consequences.
- Stage 2: *Rewards/Exchange Orientation*—Right and wrong are determined by personal needs and wants—“If I want it, it is right.”

Conventional Level: The Expectations of Society and Laws Are Taken into Account

- Stage 3: *Being Nice/Relationships Orientation*—Being good means being nice and pleasing others.
- Stage 4: *Law and Order Orientation*—Laws and authorities must be obeyed; the social system must be maintained.

Postconventional (Principled) Level: Judgments Are Based on Abstract, More Personal Principles of Justice That Are Not Necessarily Defined by Society's Laws

- Stage 5: *Social Contract Orientation*—The moral choice is determined by socially agreed upon standards—“the greatest good for the greatest number.”
- Stage 6: *Universal Ethical Principles Orientation*—There are universal principles of human dignity and social justice that individuals should uphold, regardless of the law and no matter what other people say.

Moral reasoning is related to both cognitive and emotional development. Abstract thinking becomes increasingly important in the higher stages of moral development, as children move from decisions based on absolute rules to those based on abstract principles such as justice and mercy. The ability to see another's perspective, to judge intentions, and use formal-operational thinking to imagine alternative bases for laws and rules also enters into judgments at the higher stages.

CRITICISMS OF KOHLBERG'S THEORY. In reality, Kohlberg's stages do not seem to be separate, sequenced, and consistent. People often give reasons for moral choices that reflect several different stages simultaneously. Or a person's choices in one instance may fit one stage, and his or her decisions in a different situation may reflect another stage. Thus moral decisions often are based on the situation, not on reasoning at a particular level—the reasons are made up after the fact. One of the most hotly debated criticisms of Kohlberg's theory is that the stages are biased in favor of Western male values that emphasize individualism. His stages do not represent the way moral reasoning develops either in women or in other cultures, because the stage theory was based on a longitudinal study of American men only (Gilligan, 1982; Gilligan & Attanucci, 1988; Messina & Surprenant, 2015).

Carol Gilligan (1982) proposed a different sequence of moral development, an “ethic of care.” Gilligan suggested that individuals move from a focus on self-interest to moral reasoning based on commitment to specific individuals and relationships, and then to the highest level of morality based on the principles of responsibility and care for all people. A meta-analysis that combined the results of 113 studies found only small differences in moral orientation between men and women (Jaffee & Hyde, 2000). Both men and women use *care* to reason about interpersonal dilemmas and *justice* to reason about societal dilemmas. It appears that moral reasoning is more strongly influenced by the context and content of the dilemma than by the gender of the reasoner.

Caring for students and helping students learn to care has become a theme for many educators (Goldstein & Lake, 2000). For example, Nel Noddings (1995) urged that “themes of care” be used to organize the curriculum. Possible themes include “Caring for Self,” “Caring for Family and Friends,” and “Caring for Strangers and the World.” Within the theme of “Caring for Strangers and the World,” there could be units on crime, war,

MyLab Education

The boy in this video was told a story in which a boy, Mike, finds a wallet filled with money and must decide what to do with it. What stage of moral development best characterizes his response?

poverty, tolerance, ecology, immigrants, or technology. The events after massive destructive tornadoes and hurricanes in the United States or civil wars in the Middle East that left thousands homeless or refugees might be a starting point for these units.

Another criticism of Kohlberg's stages is that they mix up moral judgments with decisions about social conventions and also overlook personal choice—distinctions described next.

Moral Judgments, Social Conventions, and Personal Choices

STOP & THINK

1. If there were no law against it, would it be OK to blind someone?
2. If there were no rule against it, would it be OK to chew gum in class?
3. Who should decide your favorite vegetable or how to style your hair? •

We probably could agree that it is wrong to blind someone, wrong to break class rules, and wrong to dictate food preferences or hairstyles for other people, but it is a different kind of “wrong” in each case. The first question is about actions that are inherently immoral. The answer to the question is concerned with conceptions of justice, fairness, human rights, and human welfare. Even young children know that it is not OK to hurt other people or steal from them—law or no law. But some rules, like no gum chewing in question 2, are **social conventions**—agreed-upon rules and ways of doing things in a particular situation. Students (mostly) avoid chewing gum when the class rules (conventions) say so. It is not inherently immoral to chew gum; it is just against the rules. Some classes—in college, for example—work well using different rules. And it is not immoral to dislike lima beans (at least I hope not) or to wear your hair long if you are a male; these are *personal choices*—individual preferences and private issues.

Larry Nucci (2001, 2009; Lagattuta, Nucci, & Bosacki, 2010) offers an explanation of moral development that covers all three domains or areas: *moral judgments*, *social conventions*, and *personal choice*. Children's thinking and reasoning develop across all domains, but the pace of development may not be the same in every area. Even the cognitive (neurological) processing of judgments in the moral and conventional domains differs (Lahat, Helwig, & Zelazo, 2013). By about age 4, children around the world make fairly firm distinctions between moral and conventions issues (Nucci, 2009).

For teachers, the most common “right and wrong” situations involve the moral and conventional domains.

MORAL VERSUS CONVENTIONAL DOMAINS. In the *moral domain*, two fundamental issues are justice and welfare/compassion (Nucci, 2009). Some of the earliest moral issues in classrooms involve dividing and sharing materials, or **distributive justice** (Damon, 1994). For young children (ages 5 to 6), fair distribution is based on equality; thus, teachers often hear, “Keshawn got more than I did—that's not fair!” In the next few years, children come to recognize that some people should get more based on merit—they worked harder or performed better. Around age 8, children can take need into account and can reason based on *benevolence*; they can understand that some students may get more time or resources from the teacher because those students have special needs. So children move through stages in reasoning about moral issues:

- A sense that justice means equal treatment for all;
- An appreciation of equity and special needs;
- A more abstract integration of equity and equality along with a sense of caring in social relations; and finally,
- As adults, a sense that morality involves both benevolence and fairness and that moral principles are independent of the norms of any particular group (Nucci, 2001, 2009).

In the *conventional domain*, children begin by believing that rules simply exist. For example, if you have spent time with young children, you know that there is a period

Social conventions

Agreed-upon rules and ways of doing things in a particular situation.

Distributive justice

Beliefs about how to divide materials or privileges fairly among members of a group; follows a sequence of development from equality to merit to benevolence.

when you can say, “Eating in front of the TV is not allowed!” and get away with it. Piaget (1965) called this the state of **moral realism**. At this stage, the child believes that rules about conduct or rules about how to play a game are absolute and can’t be changed. If a rule is broken, the child believes that the punishment should be determined by how much damage is done, not by the intention of the child or by other circumstances. So, accidentally breaking three cups is worse than intentionally breaking one, and in the child’s eyes, the punishment for the three-cup offense should be greater.

As children interact with others and see that different people have different rules, there is a gradual shift to a **morality of cooperation**. Children come to understand that people make rules and people can change them. When rules are broken, both the damage done and the intention of the offender are taken into account.

As they mature, children understand that rules, even though they are arbitrary, are made to maintain order and that people in charge make the rules. Then as students move through adolescence, they swing from understanding conventions as the appropriate ways to operate in a social system to viewing them as nothing but society’s standards that have become set because they are widely applied and seldom challenged. Finally, adults realize that conventions are useful in coordinating social life, but changeable, too. So, compared to young children, older adolescents and adults generally are more accepting of others who think differently about conventions and customs.

IMPLICATIONS FOR TEACHERS. In his book *Nice Is Not Enough*, Larry Nucci (2009) describes many specific K–12 lessons that integrate academic content with development in three domains of *moral judgments*, *social conventions*, and *personal choice*. The algebra lesson shown in Table 3.4 provides an example.

Nucci also offers several suggestions for creating a moral climate in your classroom. First, it is important to establish a community of mutual respect and warmth with a fair and consistent application of the rules. Without that kind of community, all your attempts to create a moral climate will be undermined. Second, teachers’ responses to

TABLE 3.4 • An Algebra Lesson That Also Encourages Making Moral Judgments

Students are given this scenario to discuss in pairs:

Four kids who are neighbors (John, Mark, Sally, and Mary) decide to work together on a paper route to make some money. John and Mary are both 15 and in high school, while Mark and Sally are both 12 years old and seventh graders. At the end of their first week they earn \$48. But now they have a problem. They didn’t decide ahead of time how to divide up the money that they had earned.

- a. Sally argues that the fairest way is to divide up the money equally.
- b. Mary argues that Sally was lazy and only delivered half as many papers as Mary. So Sally should get half as much as Mary and the other kids.
- c. Mark argues that he and John were stronger than Mary and Sally, who are girls, and together carried 25% more than the girls did altogether. So the boys should each get 25% more than each of the girls.
- d. John agrees that the reason Sally carried fewer papers than Mary is that she is lazy. He also argues that even though Mary isn’t as strong as the boys, she worked just as hard. However, he also argues that the older kids (he and Mary) should get 25% more than the younger kids because older kids have more expenses than younger ones do. So, in his mind, he and Mary should get the same amount and 25% more than Mark, but Sally should get half as much as Mark because she was lazy.

The Assignment

1. Please create algebraic equations that would express each solution for the best way to divide the \$48.
2. Provide a written answer for the solution you and your partner think is the fairest.
3. Explain why you think that is the fairest solution, and provide your argument as to why the other solutions are not as fair.

Moral realism Stage of development wherein children see rules as absolute.

Morality of cooperation Stage of development wherein children realize that people make rules and people can change them.

students should be appropriate to the domain of the behavior—moral or conventional. For example, here are some responses to moral issues (Nucci, 2001, p. 146):

1. When an act is inherently hurtful or unjust, emphasize the harm done to others: “John, that really hurt Jamal.”
2. Encourage perspective taking: “Chris, how would you feel if someone stole from you?”

In contrast, here are two responses to rules or conventional issues:

3. Restate the rule: “Lisa, you are not allowed to be out of your seat during announcements.”
4. Command: “Howie, stop swearing!”

In all four cases, the teacher’s response fits the domain. To create an inappropriate response, just switch responses 1 or 2 with those for 3 or 4. For example, “Lisa, how would you feel if other people got out of their seat during announcements?” Lisa might feel just fine. And it is a weak response to a moral transgression to say, “John, it is against the rules to hit.” It is more than against the rules—it hurts and it is wrong.

In the third domain—personal—children must sort out what decisions and actions are their personal choices and what decisions are outside personal choice. This process is the foundation for developing moral concepts related to individual rights, fairness, and democracy. Here, diverse cultures may have very different understandings about individual choice, privacy, and the role of individuality in the larger society.

Connect and Extend to PRAXIS II®

Moral Development (I, A2)

Moral issues can have an important impact on the classroom. Identify major issues related to moral development, and explain what a teacher can do to appropriately address these issues.

Beyond Reasoning: Haidt’s Social Intuitionist Model of Moral Psychology

In everyday life, making moral choices involves more than reasoning. Emotions, instincts, competing goals, relationships, and practical considerations all affect choices. Jonathan Haidt (2012, 2013) believes that Kohlberg overemphasized cognitive reasoning about morality. Haidt’s Social Intuitionist Model is based on research in social and evolutionary psychology and neuroscience. There are three key principles:

1. *Intuition comes first, reasoning second.* Moral reasoning is something we do only after a first automatic, emotional response (call it intuition) has pushed us toward a moral judgment of right or wrong. We instinctively feel sympathy–disgust, like–dislike, attraction–revulsion, and so on, in response to a situation or dilemma. Then we reason about why our reaction is right as we prepare to defend the choice to others, so reasoning plays a social role of maintaining our position and respect in our group. As we will see several times in this text, current perspectives on cognition decision making based on neuroscience include *dual-process models* with one system that is fast, automatic, and strongly affected by emotions and a second system that is slower, more analytic, and reflective. These dual-processing systems are at work in all human decisions and choices—including moral judgments.
2. *There is more to morality than fairness and harm.* Most theories of moral reasoning are grounded in the moral values of justice (fairness/cheating) and welfare (care/harm). Haidt believes that focusing on only these values reflects a WEIRD moral framework (Western, educated, industrialized, rich, and democratic). In WEIRD cultures, justice and human welfare are central to morality. But Haidt’s research with participants around the world has identified four other important moral values or moral foundations:
 - *Loyalty/betrayal* underlies self-sacrifice for the good of the group, patriotism, and ideas such as “no Marine left behind.”
 - *Authority/subversion* is the foundation of leadership and followership—respect for legitimate authority.
 - *Sanctity/degradation* is the foundation for striving to live a more noble and clean life and avoid contamination. Sanctity determines what objects or ideas are sacred and which ones are disgusting.
 - One other candidate for a moral foundation is *liberty/oppression*, the basis for resentment and resistance to domination, such as a hatred for bullies and dictators.

These moral foundations are present in all cultures because they evolved over thousands of years as humans lived in social groups and sought to survive. Cultures may have different ways of enacting these moral foundations, however. For example, many people in India believe the cow is sacred, and for many people in the United States the flag is sacred. So, many Indians feel disgust at harming a cow, and many Americans feel disgust when they see the U.S. flag burned. See moralfoundations.org for a description of the moral foundations.

3. *Morality binds and blinds.* When individuals in a group share the same symbols of the sacred, heroes, leaders, beliefs about right and wrong—in short, when they share the same moral beliefs—then the group is bound together. They are loyal to each other—“one for all and all for one.” They respect their leaders and each other. But in being bound together (and therefore being more likely to survive), they are blind to the moral beliefs of other groups that seem so “wrong.”

The Social Intuitionist Model is quite new, so there are few applications to education. The advantage of the model is that it fits insights from neuroscience, social psychology, and sociobiology. The model reminds us that there is more to morality than reasoning. We have an immediate instinctive reaction about what is right and wrong, and then we “reason” to justify our choice. Justifying our choices maintains our position in our group, which helped humans survive over centuries. Moral education probably needs to acknowledge the foundations of morality beyond justice and welfare and also understand the ways different cultures and groups enact those moral beliefs. Current social emotional learning approaches emphasize feelings as well as valuing and relationships (Shechtman & Yaman, 2012). Also, rather than preaching or teaching directly about moral reasoning, teachers and parents can support moral development by letting children experience and understand the natural, logical consequences of poor or hurtful choices (Messina & Surprenant, 2015)—as we will discuss in Chapter 13.

Moral Behavior and the Example of Cheating

Three important influences on moral behavior are modeling, internalization, and self-concept. First, children who have been consistently exposed to caring, generous adult models will tend to be more concerned for the rights and feelings of others (Eisenberg & Fabes, 1998; Woolfolk & Perry, 2015). Second, most theories of moral behavior assume that young children’s moral behavior is first controlled by others through direct instruction, supervision, rewards and punishments, and correction. But in time, children **internalize** the moral rules and principles of the authority figures who have guided them; that is, children adopt the external standards as their own. If children are given reasons they can understand when they are corrected—particularly reasons that highlight the effects of actions on others—then they are more likely to internalize moral principles. They learn to behave morally even when “no one is watching” (Hoffman, 2000).

Finally, we must integrate moral beliefs and values into our total sense of who we are, our self-concept.

The tendency for a person to behave morally is largely dependent on the extent to which moral beliefs and values are integrated in the personality, and in one’s sense of self. The influence our moral beliefs have on our lives, therefore, is contingent on the personal importance that we as individuals attach to them—we must identify and respect them as our own. (Arnold, 2000, p. 372)

WHO CHEATS? About 75% to 98% of college students report that they cheated in high school. In fact, the rates of academic cheating have been rising for the past 30 years, perhaps in response to increased pressures and high-stakes testing (Anderman, 2015; T. A. Murdock & Anderman, 2006).

There are some individual differences in cheating. Most studies of adolescent and college-age students find that males are more likely to cheat than females and lower-achieving students are more likely to cheat than higher achievers. Students focusing on performance goals (making good grades, looking smart) as opposed to learning goals,

Internalize Process
whereby children adopt
external standards as their
own.

students with a low sense of academic self-efficacy (a belief that they probably can't do well in school), and students who are impulsive are more likely to cheat. Finally, students who are higher on the personality traits of conscientiousness and agreeableness are less likely to cheat (Giluk & Postlethwaite, 2015).

But cheating is not all about individual differences—the situation plays a role as well. In one study, the level of cheating decreased when students moved from math classes that emphasized competition and grades to classes that emphasized understanding and mastery (Anderman & Midgley, 2004). Students are less likely to cheat when they view their teacher as credible. If students trust the teacher as a credible source, they may be more likely to value the content being taught and therefore want to actually learn it (Anderman, Cupp, & Lane, 2009). In addition, students also are particularly likely to cheat when they are behind or “cramming for tests” or when they believe that their teachers do not care about them. For example, Erica had this perspective:

I am a high school honors student, and I think there are different degrees of cheating. I'm a dedicated student, but when my history teacher bombards me with 50 questions due tomorrow or when a teacher gives me a fill-in-the-blanks worksheet on a night when I have swim practice, church, aerobics—and other homework—I'm going to copy from a friend! . . . Since I only do this when I need to, it isn't a habit. Every kid does this when they're in a pinch. (L. A. Jensen, Arnett, Feldman, & Cauffman, 2002, p. 210)

Tamera Murdock and Eric Anderman (2006) have proposed a model for integrating what we know about cheating. They suggest that in deciding to cheat, students ask three questions: What is my goal? Can I do this? What are the costs? See Table 3.5 for some example answers to these questions that might be associated with decisions about whether to cheat and some example strategies to support *not* cheating.

TABLE 3.5 • When Do Students Cheat?

Tamera Murdock and Eric Anderman have developed a model of academic cheating based on the answers to three questions.

QUESTIONS	LESS LIKELY TO CHEAT: EXAMPLE ANSWERS	MORE LIKELY TO CHEAT: EXAMPLE ANSWERS	WHAT CAN THE TEACHER DO? EXAMPLE STRATEGIES
What is my goal?	The goal is to learn, get smarter, and be the best I can be. It is my goal.	The goal is to look good, outperform others. The goal is imposed on me.	Communicate that the point of the class is to learn—everyone can get better.
Can I do it?	I can do it with reasonable effort.	I doubt my ability to do it.	Build students' confidence by helping them take small but successful steps. Point out students' past accomplishments.
What are the costs?	I will get caught and punished if I cheat. I will feel morally wrong or dishonored if I cheat.	I probably won't get caught and punished if I cheat. Everyone does it, so it can't be wrong. The pressure is too great—I can't fail. I have to cheat.	Make mistakes an opportunity to learn. Take the pressure out of assignments with the chance to revise. Avoid high-stakes tests and assignments. Provide grades privately. Monitor to prevent cheating, and follow through with reasonable penalties.

Source: Adapted from Murdock and Anderman (2006).

DEALING WITH CHEATING. The implications for teachers are straightforward. To prevent cheating, try to avoid putting students in high-pressure situations. Make sure they are well prepared for tests, projects, and assignments so they can do reasonably well without cheating. Be a trustworthy and credible source of information. Focus on learning and not on grades. Encourage collaboration on assignments and experiment with open-book, collaborative, or take-home tests. I often tell my students what concepts will be on the test and encourage them to discuss the concepts and their applications before the test. You might also make extra help available for those who need it. Be clear about your policies in regard to cheating, and enforce them consistently. Help students to resist temptation by monitoring them carefully during testing.

MyLab Education Self-Check 3.4

PERSONAL/SOCIAL DEVELOPMENT: LESSONS FOR TEACHERS

Both Erikson and Bronfenbrenner stress that individuals are influenced by their social and cultural contexts. For example, here are a few big ideas:

1. Students whose parents are divorcing can benefit from authoritative teachers who are both warm and clear about requirements.
2. For all students, self-concepts are increasingly differentiated over time—they may feel competent in one subject, but not in others, or very capable as friends or family members, but not good about work in school.
3. For all students, it is a challenge to forge a meaningful identity that integrates their decisions about career, religion, ethnicity, gender roles, and connection to society. Teachers are in a position to support this quest.
4. Being rejected by peers is harmful for all students. Many students need guidance in developing social skills, in more accurately reading the intentions of others, in resolving conflicts, and in coping with aggression. Again, teachers can provide guidance.
5. When working under high pressure, with unreasonable workloads, and with little chance of being caught, many students will cheat. It is up to teachers and schools to avoid these conditions.

▼ SUMMARY

Physical Development (pp. 102–108)

Describe the changes in physical development of children in the preschool, elementary, and secondary grades. During the preschool years, there is rapid development of children's gross- and fine-motor skills. Physical development continues throughout the elementary school years, with girls often ahead of boys in size. With adolescence comes puberty and emotional struggles to cope with all the related changes.

What are some of the consequences of early and late maturation for boys and girls? Females mature about 2 years ahead of males. Early-maturing boys are more likely to enjoy high social status; they tend to be popular and to be leaders. But they also tend to engage in more delinquent behavior—this is true for White, African American, and Mexican American boys. Early maturation is not generally beneficial for girls.

What is the role of recess and physical activity in development? Forms of play vary across cultures, but play still supports brain development, language, and social development. Children release tensions, learn to solve problems, adapt to new situations, cooperate, and negotiate. The increase in

childhood obesity is linked to inactivity and increased time spent watching TV and playing passive games such as video and Internet games. Other dangers today include the risk of concussions in contact sports.

What are some of the signs of eating disorders? Anorexic students may appear pale, have brittle fingernails, and have fine dark hairs developing all over their bodies. They are easily chilled because they have so little fat to insulate their bodies. They often are depressed, insecure, moody, and lonely. Girls may stop having their menstrual period.

Bronfenbrenner: The Social Context for Development (pp. 108–123)

Describe Bronfenbrenner's bioecological model of development. Bronfenbrenner's model takes into account both the biological aspects internal to the individual and the nested social and cultural contexts that shape development. Every person develops within a microsystem (immediate relationships and

activities) inside a mesosystem (relationships among microsystems), embedded in an exosystem (larger social settings such as communities); all of these are part of the macrosystem (culture). In addition, all development occurs in and is influenced by the time period—the chronosystem.

What are some aspects of the family that affect students in school? Students probably have experienced different parenting styles, and these styles can influence their social adjustment. At least in European American, middle-class families, children of authoritative parents are more likely to be happy with themselves and relate well to others, whereas children of authoritarian parents are more likely to feel guilty or depressed, and children of permissive parents may have trouble interacting with peers. But cultures also differ in parenting styles. Research indicates that higher-control parenting is linked to better grades for Asian and African American students. Children in every culture form attachments, even though parents in different cultures may nurture attachments in different ways. The quality of these attachment bonds has implications for forming relationships throughout life.

How does divorce affect students? During the divorce itself, conflict may increase as property and custody rights are being decided. After the divorce, the custodial parent may have to move to a less expensive home, go to work for the first time, or work longer hours. For the child, this can mean leaving behind important friendships just when support is needed the most, having only one parent who has less time than ever to be with them, or adjusting to new family structures when parents remarry.

Why are peer relationships important? Peer relationships play a significant role in healthy personal and social development. Strong evidence shows that adults who had close friends as children have higher self-esteem and are more capable of maintaining intimate relationships than adults who had lonely childhoods. Adults who were rejected as children tend to have more problems, such as dropping out of school or committing crimes.

What are peer cultures? Groups of students develop their own norms for appearance and social behavior. Group loyalties can lead to rejection for some students, leaving them upset and unhappy.

What are the different types of aggression? Peer aggression can be instrumental (intended to gain an object or privilege), or hostile (intended to inflict harm). Hostile aggression can be either overt threats or physical attacks, or relational aggression, which involves threatening or damaging social relationships. Boys are more likely to use overt aggression, and girls are more likely to use relational aggression. Today the many social media applications and sites provide other avenues for relational aggression.

How does ever-present media affect aggression and empathy? The world and the media provide many negative models of behavior. In time, children internalize the moral rules and principles of the authority figures who have guided them. If children are given reasons—particularly reasons that highlight the effects of actions on others—they can understand when they are corrected and are more likely to internalize moral principles. Some schools have adopted programs to increase students' capacity to care for others.

How can teachers' academic and personal caring affect students? Students value caring in teachers. Caring can be expressed as support for academic learning and as concern

for personal problems. For students who are higher achieving and have higher socioeconomic status, academic caring may be more important, but for students who are alienated from school, personal caring may be more important.

What are some signs of child abuse? Signs of abuse or neglect include unexplained bruises, burns, bites, or other injuries; fatigue; depression; frequent absences; poor hygiene; inappropriate clothing; problems with peers; and many others. Teachers must report suspected cases of child abuse and can be instrumental in helping students cope with other risks as well.

Identity and Self-Concept (pp. 123–135)

What are Erikson's stages of psychosocial development? Erikson's emphasis on the relationship between society and the individual is a psychosocial theory of development—a theory that connects personal development (*psycho*) to the social environment (*social*). Erikson believed that people go through eight life stages, each of which involves a central crisis. Adequate resolution of each crisis leads to greater personal and social competence and a stronger foundation for solving future crises. In the first two stages, an infant must develop a sense of trust over mistrust and a sense of autonomy over shame and doubt. In early childhood, the focus of the third stage is on developing initiative and avoiding feelings of guilt. In the child's elementary school years, the fourth stage involves achieving a sense of industry and avoiding feelings of inferiority. In the fifth stage, identity versus role confusion, adolescents consciously attempt to solidify their identity. According to Marcia, these efforts may lead to identity diffusion, foreclosure, moratorium, or achievement. Erikson's three stages of adulthood involve struggles to achieve intimacy, generativity, and integrity.

Describe the formation of ethnic and racial identities. Ethnic and racial minority students are confronted with the challenge of forming an identity while living in two worlds—the values, beliefs, and behaviors of their group and those of the larger culture. Most explanations for identity development describe stages moving from being unaware of differences between minority group and majority cultures, to different ways of negotiating the differences, and finally to an integration of cultures. Identity can be multidimensional for many students—they identify with different ethnic backgrounds, countries, or cultures.

How does self-concept change as children develop? Self-concept (definition of self) becomes increasingly complex, differentiated, and abstract as we mature. Self-concept evolves through constant self-reflection, social interaction, and experiences in and out of school. Students develop a self-concept by comparing themselves to personal (internal) standards and social (external) standards. Self-concepts in specific academic areas (math, languages, science, etc.) are related to performance in those areas. Gender and ethnic stereotypes are significant factors as well.

What is self-esteem? In the hierarchical model of self-concept, self-esteem is at the top. Self-esteem is an overall judgment of self-worth that includes feeling proud or ashamed of yourself as a person. Thus self-esteem is the *evaluative* dimension of self-concept. Self-concept and self-esteem are often used interchangeably, even though they have distinct meanings. Self-concept is a cognitive structure, and self-esteem is the evaluative component of self-concept.

Are there differences in self-concepts for girls and boys?

From first to twelfth grade, competence beliefs decline for both boys and girls in math, language arts, and sports. By high school, boys and girls express about the same competence in math, girls are higher in language arts, and boys are higher in sports. In terms of general self-esteem, both boys and girls report declines in the transition to middle school, but boys' self-esteem goes up in high school while girls' self-esteem stays down.

Understanding Others and Moral Development (pp. 135–143)

What is a theory of mind, and why is it important? A theory of mind is an understanding that other people are people too, with their own minds, thoughts, feelings, beliefs, desires, and perceptions. Children need a theory of mind to make sense of other people's behavior. As children develop a theory of mind, they can also understand that other people have intentions of their own.

How do perspective-taking skills change as students mature?

An understanding of intentions develops as children mature, but aggressive students often have trouble understanding the intentions of others. Social perspective taking also changes as we mature. Young children believe that everyone has the same thoughts and feelings they do. Later, they learn that others have separate identities and therefore separate feelings and perspectives.

What are the key differences among the preconventional, conventional, and postconventional levels of moral reasoning?

Kohlberg's theory of moral development includes three levels: (1) a preconventional level, where judgments are based on self-interest; (2) a conventional level, where judgments are based on traditional family values and social expectations; and (3) a postconventional level, where judgments are based on more abstract and personal ethical principles. Critics suggest that Kohlberg's view does not account for possible cultural differences in moral reasoning or differences between moral reasoning and moral behavior.

Describe Gilligan's levels of moral reasoning. Carol Gilligan has suggested that because Kohlberg's stage theory was based on a

longitudinal study of men only, it is very possible that the moral reasoning of women and the stages of women's development were not adequately represented. She has proposed an "ethic of care" in which individuals move from a focus on self-interest to moral reasoning based on commitment to specific individuals and relationships, and then to the highest level of morality based on the principles of responsibility and care for all people.

How does thinking in the moral and conventional domains change over time? Beliefs about morality move from the young child's sense that justice means equal treatment for all to the adult's understanding that morality involves beneficence and fairness and that moral principles are independent of the norms of any particular group. In thinking about social conventions, children begin by believing that the regularities they see are real and right. After going through several stages, adults realize that conventions are useful in coordinating social life, but changeable too.

What has Haidt added to our understanding of moral behavior?

In everyday life, making moral choices involves emotions, instincts, competing goals, relationships, and practical considerations. Haidt suggests that instincts in relation to fairness, loyalty, authority, a sense of the sacred, and liberty lead to more automatic, emotional reactions to moral situations, then we construct reasons for our reactions. Cultures vary in their moral values. These values bind groups together, but also blind them to the moral beliefs of other groups.

What influences moral behavior? Adults first control young children's moral behavior through direct instruction, supervision, rewards and punishments, and correction. A second important influence on the development of moral behavior is modeling. Children who have been consistently exposed to caring, generous adult models will tend to be more concerned for the rights and feelings of others.

Why do students cheat? In schools, cheating is a common behavior problem that involves moral issues. The decision to cheat is based on three questions: What is my goal? Can I do this? What are the costs? Cheating is caused by both individual and situational factors, but if the pressure is great enough and the chance of getting caught is slim, many students will cheat.

MULTIPLE-CHOICE QUESTIONS

- Mr. Thomas expected his students to score high and imposed detention on students who scored below 80%. He believed that students should spend most of their time learning, and, as a result, he assigned extra homework to all his students. He also strongly discouraged student from going out to play, and reprimanded them when they were caught engaging in non-academic activities during their leisure time. Mr. Thomas is best described as a teacher with:
 - authoritative teaching style.
 - authoritarian teaching style.
 - permissive teaching style.
 - rejecting teaching style.
- Which of the following about classroom aggression is FALSE?
 - Some students who are socially rejected by their peer groups tend to become aggressive, and such tendencies sometimes persist into adulthood.
 - The onset of classroom aggression in middle school students is not sudden; children's aggressive tendencies can often be traced back to as early as elementary school.
 - Boys are more likely to engage in overt aggression (e.g., threats or physical attack), while girls are more inclined to perform relational aggression (e.g., acts which aim at damaging social relationship).
 - Students who occasionally behave aggressively are rejected by their peers and, as a result, never have friends to support them in school.

- Which of the following students is LEAST likely to cheat in an exam?

- Julia, who wants to impress her teacher by keeping her status as the star student
- Randi, who aims to do well in an exam as expected by her parents and family
- Wenhao, who is instructed by his parents to recite the moral code of honesty every now and then
- Shin, who wants to be the best she can be

CONSTRUCTED-RESPONSE QUESTIONS

Case

Suzanne Wilson entered Ms. Sullivan's class in the fall without any friends. While many of the third-graders engaged in collaborative games on the playground, Suzanne stood on the periphery, and the other students did not include her. In class her behaviors were more typical of a younger child, sucking her thumb when she became upset and refusing to share during group activities. By December, Ms. Sullivan decided to take steps to intervene. She called Mr. and Mrs. Wilson for a parent meeting. When the Wilsons arrived, Suzanne was with them. What then transpired was shocking to Ms. Sullivan. Suzanne adamantly insisted that her parents not talk with her teacher in private. Yelling above the crying and screaming, the Wilsons apologized and suggested they return on another day when Suzanne was feeling more agreeable.

- Identify and explain the parenting style the Wilsons appear to practice.
- What strategies should Ms. Sullivan employ to assist Suzanne with her emotional development?

▼ WHAT WOULD THEY DO?

TEACHERS' CASEBOOK: Mean Girls

Here is how several expert teachers said they would address the situation with Alison and the clique of "mean girls."

THOMAS NAISMITH • Science Teacher, Grades 7–12

Slocum Independent School District, Elkhart, TX

To bring civility to this classroom, I would address the situation in two stages. First, I would meet individually with the two girls involved in the most recent incident. I would make it very clear to Alison that her behavior was totally inappropriate and that such behavior was far beneath her. I would suggest to her that I was sure that it was just a temporary lapse of good judgment on her part and that I was sure that such an incident would not occur again. I would also ask her to play a role in helping to stop some of the other inappropriate behavior that was occurring in my classroom.

I would explain to Stephanie that she did not need to be embarrassed, because her classmates would appreciate the fact that she had made an effort to restore an old "friendship." I would comment on her positive qualities, explain that she should feel good about herself, and suggest that she seek the companionship of students who are open to her friendship.

The second step would be to address the class as a whole. I would be nonspecific in my comments, but I would make it very clear that the gossip and other "ugly" behavior would need to stop. I would explain that our classroom is a mini-society and that every member has the responsibility of treating others appropriately. I would further explain that they did not have to be "friends" with everyone but should treat everyone with respect and dignity.

JACALYN D. WALKER • Eighth-Grade Science Teacher

Treasure Mountain Middle School, Park City, UT

Never work in a vacuum. This is especially important in a middle school or junior high school. Work with your school counselor, other grade-level teachers, and parents. If you are doing this, you will have several options for dealing with this problem. You cannot fake caring about 12-, 13-, and 14-year-olds. They can spot a fake. You must be working with this age group because you truly like them as people. You appreciate their humor and their abilities. With a caring, trusting, and respectful relationship, students will be open to your help and guidance. Parents

are often not involved in the classroom at these grade levels, but there are great programs available to get parents involved.

NANCY SCHAEFER • Grades 9–12

Cincinnati Hills Christian Academy High School, Cincinnati, OH

I would first make a phone call to Stephanie's home. Under the guise of calling about assignments because of the days she has missed, I would talk to one of her parents or guardians. My first goal would be to find out if the parents are aware of the situation. Sometimes girls like Stephanie are too embarrassed to tell their parents the whole story or even any of the real story. If the parents did not know the entire story, I might try to get Stephanie on the phone and help her tell her parents. Letting the adults around her know what has happened can relieve some of the shame she might be feeling.

I would then work with Stephanie and one or more of her parents to plan Stephanie's transition back to school. A school counselor might also be involved in this conversation. The adults would help Stephanie come up with a plan for how to handle possible difficult situations: face-to-face encounters with Alison, encounters with other old "friends," mean messages she might receive during the school day, or comments made to her by other students. We would help her think through these situations and practice how she could respond. I could talk to Stephanie's teachers to work on rearranging groups or seating to move the girls away from each other or to foster other friendships for Stephanie. Because almost every one has stories about unfaithful friends, Stephanie might benefit from talking with a freshman or sophomore about that person's experiences and how he or she made new friends. Finally, I would try to arrange a brief and supervised meeting between Stephanie and Alison. Allowing an encounter to happen in a controlled environment would provide Stephanie an outlet to voice her hurt, without her having to resort to inappropriate actions.

During all of this, I would want to make sure that someone was also working with Alison, to prevent the escalation of events. This may be an administrator responsible for discipline, if school rules were violated; the school counselor; or another teacher with a good relationship with Alison. I would encourage the involvement of Alison's parents, especially if this were not the first vicious episode.

chapter four

LEARNER DIFFERENCES AND LEARNING NEEDS

WHAT WOULD YOU DO?

TEACHERS' CASEBOOK: Including Every student

It is a new school year, and your district has had a change in policy. "Special Education" programs have been discontinued and ALL students will now be included in general education classrooms full time. You knew that you were going to have students with a wide range of abilities, social skills, and motivation for learning in your classroom, but now you also have a student with severe asthma, a fairly high-functioning student with Asperger syndrome, a student with severe learning disabilities, and two students who are on medication for attention-deficit hyperactivity disorder (ADHD). It is not clear what resources will be available to you, but even so, you want to face this challenge with confidence and a sense of efficacy for teaching all students.

CRITICAL THINKING

- How will you design a standards-based curriculum that will allow all of the students to learn to their fullest potential and demonstrate proficiency toward the standards?
- What can you do to address the specific problems of your students who have been identified with special needs?
- How will you remain confident in your new situation?

Anita Woolfolk Hoy

OVERVIEW AND OBJECTIVES

To answer the critical thinking questions, you need an understanding of individual differences. So far, we have not talked much about individuals. We have discussed principles of development that apply to everyone—stages, processes, conflicts, and tasks. Our development as human beings is similar in many ways, but not in every way. Even among members of the same family, there are marked contrasts in appearance, interests, abilities, and temperament, and these differences have important implications for teaching. We will spend some time analyzing the concepts of intelligence, creativity, and learning styles because these terms are so often misunderstood. You probably will have at least one student with special needs in your class, whatever grade you teach, so in this chapter we also explore both common and less frequently occurring learning problems. As we discuss each situation, we will consider how a teacher might recognize problems, seek help, and plan instruction, including using the approach of response to intervention. By the time you have completed this chapter, you should be able to:

- Objective 4.1 Describe current theories of intelligence including the advantages and disadvantages of labeling, hierarchical and multiple theories of intelligence, how intelligence is measured, and what these measurements tell teachers.
- Objective 4.2 Explain how creativity is defined, assessed, and encouraged in the classroom.
- Objective 4.3 Discuss the values and limitations of considering students' learning styles.
- Objective 4.4 Discuss the implications of the IDEA and Section 504 protections for contemporary education.
- Objective 4.5 Understand and address the special educational needs of students with learning challenges.
- Objective 4.6 Recognize and respond to the special educational needs of students who are gifted and talented.

- Identifying Students Who Are Gifted and Talented
- Teaching Students with Gifts and Talents

Summary and Key Terms

Teachers' Casebook—Including Every Student: What Would They Do?

INTELLIGENCE

Because the concept of intelligence is so important, so controversial, and so often misunderstood in education, we will spend quite a few pages discussing it. But before we begin, let's examine the practice of labeling people based on differences such as intelligence or disability.

Language and Labels

Every child is a distinctive collection of talents, abilities, and limitations. Some students have learning disabilities, emotional or behavioral disorders, intellectual disabilities, physical disabilities, autism spectrum disorders, remarkable gifts and talents, or a combination of them. Even though we will use terms like these throughout the chapter, a caution is in order: *Labeling students is a controversial issue.*

A label does not tell which methods to use with individual students. For example, few specific "treatments" automatically follow from a "diagnosis" of behavioral disorder; many different teaching strategies and materials are appropriate. Further, the labels can become self-fulfilling prophecies. Everyone—teachers, parents, classmates, and even the students themselves—may see a label as a stigma that cannot be changed. Evidence indicates, for example, that high school teachers and counselors guide students labeled *learning disabled* into less-demanding courses than their actual abilities would warrant. The label itself seems to affect the guidance. Courses taken in high school are gateways to college and advanced education, so lower expectations for students—which lead to enrollment in less-demanding courses—can have a life-changing impact (D. Rice & Muller, 2013). Finally, labels are mistaken for explanations, as in, "Santiago gets into fights because he has a behavior disorder." "How do you know he has a behavior disorder?" "Because he gets into fights" (Friend, 2014).

On the other hand, some educators argue that for younger students, at least, being labeled as "special needs" protects the child. For example, if classmates know a student has an intellectual disability (once called *mental retardation*), they will be more willing to accept his or her behaviors and be supportive. Of course, diagnostic labels still open doors to some programs, useful information, adaptive technology and equipment, or financial assistance. Labels probably both stigmatize and help students (Scruggs & Mastropieri, 2013).

DISABILITIES AND HANDICAPS. A **disability** is just what the word implies—an *inability* to do something specific such as pronounce words or see or walk. A **handicap** is a *disadvantage* in certain situations. Some disabilities lead to handicaps, but not in all contexts. For example, being blind (a visual disability) is a handicap if you want to drive a car, but not when you are composing music or talking on the telephone. Stephen Hawking, the greatest living physicist, has Lou Gehrig's disease and no longer can move or talk.

He once said that he is lucky that he became a theoretical physicist “because it is all in the mind. So my disability has not been a serious handicap.” It is important that we do not create *handicaps* for people by the way we react to their *disabilities*. Some educators have suggested that we drop the word *handicap* altogether because the source of the word is demeaning. *Handicap* came from the phrase “cap-in-hand,” used to describe people with disabilities who once were forced to beg just to survive (Hardman, Drew, & Egan, 2014). We can think of all human characteristics as being on a continuum, for instance, from very acute hearing to complete deafness. We all fall somewhere on that continuum, and our position on the continuum changes over our lifetimes, as my husband will readily tell you about my hearing!

When speaking about a person with a disability, it is important that we avoid the language of pity, as in “confined to a wheelchair” or “victim of AIDS.” Wheelchairs are not confining. They allow people to get around. Using “victim of” or “suffering with” makes the person seem powerless. On their resources Web site, the United Spinal Association offers a free pdf booklet with many ideas about disability. Every teacher should have it. Go to <http://unitedspinal.org> and search for Disability Etiquette in their Reading Room. See Figure 4.1 for an example.

Another way of showing respect to individuals with disabilities is to use “person-first” language.

PERSON-FIRST LANGUAGE. You may have heard or even said terms like “emotionally disturbed student” or “at-risk student.” Actually, the individual has many characteristics and abilities, and to focus on the disability is to misrepresent the individual. An alternative is “person-first” language or speaking of “students with a behavior disorder” or “students placed at risk.” Here, the emphasis is on the students first.

FIGURE 4.1

DISABILITY ETIQUETTE

Disability The inability to do something specific such as walk or hear.

Handicap A disadvantage in a particular situation, sometimes caused by a disability.

Students with learning disabilities	NOT	Learning disabled students
Students receiving special education	NOT	Special education students
A person with epilepsy	NOT	An epileptic
A child with a physical disability	NOT	A crippled child
Children diagnosed with autism	NOT	Autistic children or autistics

Be aware, however, that some people with disabilities prefer an **identity-first reference**. They believe that the disability is part of their identity; they “claim” the disability as their own and value it as a part of who they are. It is a source of pride to be part of that culture. As the colleague of one psychologist said, “I am absolutely not a ‘person with autism.’ It’s [the autism] not detachable” (Dunn & Andrews, 2015, p. 257). As you will see later in the chapter, many people with hearing losses prefer to be called *deaf*—they are proud to be part of the deaf culture. The best advice for teachers probably is to use person-first language in writing, but check with individuals about how they like to be described in person (Dunn & Andrews, 2015).

POSSIBLE BIASES IN THE APPLICATION OF LABELS. Many good assessments and careful procedures are available to identify students with disabilities and to use labels properly, but do these assessments and procedures work well for racial, ethnic, and language minority students? For years, researchers and policy makers believed that racial, ethnic, and language minority students were *overrepresented* in the disability categories, and that racial or ethnic bias was the cause (Friend, 2014; U.S. Department of Education, 2015). A large study that followed over 20,000 students from kindergarten through eighth grade found just the opposite—*underrepresentation*. “Instead, we consistently found that racial-, ethnic-, and language-minority schoolchildren are comparatively underidentified as having disabilities and so are underrepresented in special education as they attend elementary and middle schools in the United States” (Morgan et al., 2015, p. 288). These researchers noted that the differences in representation between White and minority group students might mean that White students were actually overidentified for special services. Are White parents more likely to seek help? Are professionals such as pediatricians or school psychologists more likely to recommend services for White, English-speaking children? Are parents of racial, ethnic, and language minority students reluctant to add a label that they feel will stigmatize their child? Do they mistrust schools?

No matter what the situation—overidentification or underidentification—two questions remain. Are racial, ethnic, and language minority students being well served by the schools? Are any differences between the way White students and minority group students are served the result of biases? Before making a formal referral, be sure to gather a range of information about a student such as the student’s level of English proficiency and any unusual stressors such as being homeless. Having more knowledge about the student and his or her circumstances outside of school should help teachers make better decisions about what programs are appropriate (Gonzalez, Brusca-Vega, & Yawkey, 1997; National Alliance of Black School Educators, 2002).

Intelligence is widely used in placement decisions and as a label in life in general. Let’s begin with a basic question. . . .

What Does Intelligence Mean?

STOP & THINK Who was the most intelligent person in your high school? Write down a name and the first 4 or 5 words that come to mind when you see that person in your mind’s eye. What made you pick this individual? •

The idea that people vary in what we call **intelligence** has been with us for a long time. Most early theories about the nature of intelligence involved one or more of the following

Identity-first

reference Using terms such as “autistic” or “deaf” to describe a person—some people prefer this reference because they “claim” the disability as their own and value it as a part of who they are. It is a source of pride to be part of that culture.

Intelligence Ability or abilities to acquire and use knowledge for solving problems and adapting to the world.

three themes: (1) the capacity to learn; (2) the total knowledge a person has acquired; and (3) the ability to adapt successfully to new situations and to the environment in general. Notice how even these early definitions signal *that intelligence can be increased* because it includes the total knowledge you have acquired. A definition that captures these elements and stresses higher-order thinking states that intelligence is “the ability to reason deductively or inductively, think abstractly, use analogies, synthesize information, and apply it to new domains” (Kanazawa, 2010, p. 281).

INTELLIGENCE: ONE ABILITY OR MANY? There are moderate-to-high correlations among scores on *all* cognitive tests. Because of these persistent intercorrelations, some psychologists believe intelligence is a basic ability that affects performance on all cognitively oriented tasks, from solving mathematical problems to analyzing poetry to taking history essay examinations. What could explain these results? Charles Spearman (1927) suggested that individuals use mental energy, which he called *g*, to perform any cognitive test. Spearman added that each test also requires some specific abilities as well—so ability to do any mental task is based on *g* + task-specific abilities. We can mathematically compute a common factor (*g*) across cognitive tests, but this computed factor is simply an indication or measure of **general intelligence**; it is not general intelligence itself. So the notion of *g* *does not tell us what intelligence is or where it comes from* (Blair, 2006; Kanazawa, 2010).

Raymond Cattell and John Horn’s theory of *fluid and crystallized intelligence* is more helpful in providing explanations of what intelligence is (Cattell, 1963; Horn, 1998; Kanazawa, 2010). **Fluid intelligence** is mental efficiency and the reasoning ability included in Kanazawa’s definition of intelligence just quoted. The neurophysiological underpinnings of fluid intelligence may be related to changes in brain volume, myelination (coating of neural fibers that makes processing faster), the density of dopamine receptors, or processing abilities in the prefrontal lobe of the brain such as selective attention and especially *working memory*, an aspect of brain functioning we will explore in Chapter 8 (Tourva, Spanoudis, & Demetriou, 2016; Waterhouse, 2006). This aspect of intelligence increases until late adolescence (about age 22) because it is grounded in brain development, and then declines gradually with age. Fluid intelligence is sensitive to injuries and diseases of the brain and neurological system.

In contrast, **crystallized intelligence** is the ability to apply the problem-solving methods appropriate in your cultural context—the “application to new domains” part of Kanazawa’s definition of intelligence. Crystallized intelligence can increase throughout the life span because it includes learned skills and knowledge such as reading, memorizing facts, and knowing how to use Uber, troubleshoot technology problems, make a quilt, or design a unit on symbolism in poetry. By *investing fluid intelligence* in solving problems, we *develop our crystallized intelligence*, but many tasks in life such as mathematical reasoning draw on both fluid and crystallized intelligence working together (Ferrer & McArdle, 2004; Finkel, Reynolds, McArdle, Gatz, & Pedersen, 2003; Hunt, 2000).

The most widely accepted view today based on testing a wide range of mental abilities is that intelligence, like self-concept, has many facets and is a hierarchy of abilities, with general ability at the top and more specific abilities at lower levels of the hierarchy (Schalke et al., 2013; Tucker-Drob, 2009). John Carroll (1997) identifies one general ability, a few broad abilities (e.g., fluid and crystallized abilities, learning and memory, visual and auditory perception, and processing speed), and at least 70 specific abilities such as language development, memory span, and simple reaction time. General ability may be related to the maturation and functioning of the frontal lobe of the brain, while specific abilities may be connected to other parts of the brain (Byrnes & Fox, 1998).

Another View: Gardner’s Multiple Intelligences

While Howard Gardner was a developmental psychologist doing research with two very different groups—students who were artistically gifted at Harvard’s Project Zero and patients with brain injuries at Boston’s Veterans Administration (VA) Medical Center—he started thinking about a new theory of intelligence. Time and time again at the VA

Connect and Extend to PRAXIS II®

Multiple Intelligences (I, B1)

Many teachers erroneously assume that they must address each of the eight intelligences in each lesson they design. What are some of the realistic implications of the theory for classroom instruction?

General intelligence (*g*) A

general factor in cognitive ability that is related in varying degrees to performance on all mental tests.

Fluid intelligence Mental efficiency, nonverbal abilities grounded in brain development.

Crystallized intelligence Ability to apply culturally approved problem-solving methods.

Medical Center, Gardner observed brain-injured patients who were lost spatially but could do all kinds of verbal tasks, and other patients who had the opposite set of abilities and problems. He also worked with young children at Project Zero who could draw expertly but not craft a good sentence and vice versa. Gardner concluded that several separate mental abilities exist, and from this idea he developed his now-famous **theory of multiple intelligences (MI)** that describes at least eight separate intelligences (1983, 2003, 2009, 2011).

As you will see later in this chapter, even though research has not supported the existence of eight separate abilities, Gardner's ideas have been very influential. Let's look first at the ideas, then consider the research findings and criticisms, and finally address any insights for teachers.

WHAT ARE THESE INTELLIGENCES? The eight intelligences in MI theory are linguistic (verbal), musical, spatial, logical-mathematical, bodily-kinesthetic (movement), interpersonal (understanding others), intrapersonal (understanding self), and naturalist (observing and understanding natural and human-made patterns and systems). Gardner stresses that there may be more kinds of intelligence—eight is not a magic number. He has speculated that there may be a spiritual intelligence and an existential intelligence—the abilities to contemplate big questions about the meaning of life (Gardner, 2009, 2011). As Gardner witnessed firsthand in his early research with veterans and students, individuals may excel in one of these eight areas, but have no remarkable abilities, or may even have problems, in the other seven. Also, varying cultures and eras of history place different values on the eight intelligences. A naturalist intelligence is critical in farming cultures, whereas verbal and mathematical intelligences are important in technological cultures.

Table 4.1 summarizes these eight (or nine) intelligences.

CRITICS OF MULTIPLE INTELLIGENCES THEORY. Gardner's MI theory has not received wide acceptance in the scientific community, even though many educators embrace it. Virtually no published studies validate MI theory (Waterhouse, 2006). The eight intelligences are not independent; there are correlations among the abilities. In fact, logical-mathematical and spatial intelligences are highly correlated. Purely cognitive skills such as logical-mathematical, linguist, and spatial abilities are closely related to and influenced by *g*, or general intelligence (Castejon, Perez, & Gilar, 2010; Sattler, 2008; Visser, Ashton, & Vernon, 2006). Evidence linking musical and spatial abilities has prompted Gardner to consider that there may be connections among the intelligences (Gardner, 1998, 2003). So, these “separate abilities” may not be so separate after all. In addition, some critics suggest that several intelligences are really talents (bodily-kinesthetic skill, musical ability) or personality traits (interpersonal ability). Other “intelligences” are not new at all. Many researchers have identified verbal and spatial abilities as elements of intelligence. Daniel Willingham (2004) has been even more blunt. “In the end, Gardner's theory is not that helpful. For scientists the theory is almost certainly incorrect. For educators, the daring applications forwarded by others in Gardner's name (and of which he disapproves) are unlikely to help students” (p. 24).

GARDNER RESPONDS. Gardner's supporters say he based his theory on a wide range of research in several fields including psychology, anthropology, and biology (Castejon et al., 2010). In addition, Gardner (2003, 2009) also has responded to critics by identifying a number of myths, misconceptions, and misuses related to MI theory and schooling. For example, he stresses that an intelligence is not the same as a sensory system; there is no “auditory intelligence” or “visual intelligence.” Intelligences are not the same as learning styles. (Gardner doesn't believe that people actually have consistent learning styles.) Another misconception is that MI theory disproves the idea of general intelligence. Gardner does not deny the existence of a general ability, but he does question how useful general intelligence is as an explanation for human achievements. Stay tuned for more developments.

MyLab Education
Video Example 4.1

In this video, a seventh grade science teacher incorporates several of the multiple intelligences into his assessments. Is this teacher using Gardner's theory to foster effective learning?

Theory of multiple intelligences (MI) In Gardner's theory of intelligence, a person's eight separate abilities: logical-mathematical, linguistic, musical, spatial, bodily-kinesthetic, interpersonal, intrapersonal, and naturalist.

TABLE 4.1 • **Eight (or Nine) Intelligences**

Howard Gardner's theory of multiple intelligences suggests that there are eight or nine kinds of human abilities. An individual might have strengths or weaknesses in one or several areas.

LOGICAL-MATHEMATICAL Skills: • Sensitivity to, and capacity to discern, logical or numerical patterns. • Ability to handle long chains of reasoning. Example/Career Paths: Scientist Mathematician Engineer	LINGUISTIC Skills: • Sensitivity to sounds, rhythms, and word meanings. • Sensitivity to different functions of language. Example/Career Paths: Poet Journalist Novelist
MUSICAL Skills: • Ability to appreciate and produce rhythm, tone, pitch, and timbre. • Appreciation of forms of musical expression. Example/Career Paths: Composer Pianist Drummer	SPATIAL Skills: • Ability to perceive the visual and spatial world accurately. • Ability to perform transformations on those perceptions. Example/Career Paths: Sculptor Navigator Architect
INTERPERSONAL Skills: • Ability to read the moods and motivations of others. • Ability to understand desires and needs of others and respond appropriately. Example/Career Paths: Therapist Salesperson Mediator	INTRAPERSONAL Skills: • Knowledge of your own strengths, weaknesses, capabilities, and needs and ability to use these to guide your behavior. • Access to your own feelings. Example: Anyone with detailed, accurate knowledge of himself or herself
NATURALIST Skills: • Ability to recognize plants and animals. • Ability to use categories and systems to understand the natural world. Example/Career Paths: Farmer Gardener Animal tracker	BODILY-KINESTHETIC Skills: • Ability to control body movements and know where your body is in space. • Ability to handle objects skillfully. Example/Career Paths: Dancer Gymnast Juggler
EXISTENTIAL Skills: • Ability to consider and examine deeper or larger questions about human existence and the meaning of life. • Ability to understand religious and spiritual ideas. Example/Career Paths: Philosopher Clergy Life coaches	

Source: Based on "Multiple Intelligences Go to School," by H. Gardner and T. Hatch (1989), *Educational Researcher*, 18(8), and "Are There Additional Intelligences? The Case for the Naturalist, Spiritual, and Existential Intelligences," by H. Gardner (1999) in J. Kane (Ed.), *Educational Information and Transformation*, Upper Saddle River, NJ: Prentice-Hall.

MULTIPLE INTELLIGENCES GO TO SCHOOL. First let's consider a few misuses of MI theory in schools. Gardner particularly deplored an educational project in Australia that proclaimed different ethnic groups had certain specific intelligences but lacked others. Gardner went on television in Australia to call this program what it really

was—“pseudoscience” and “veiled racism” (Gardner, 2009, p. 7). The project was cancelled. Another misuse is that some teachers embrace a simplistic version of Gardner’s theory. They include every “intelligence” in every lesson, no matter how inappropriate.

A better way to use the theory is to focus on six Entry Points—narrative, logical-quantitative, aesthetic, experiential, interpersonal, and existential/foundational—in designing a curriculum (Gardner, 2006; Wares, 2013). For example, to teach about evolution, teachers might use the Entry Points as follows (Kornhaber, Fierros, & Veenema, 2004):

Narrative: Provide rich stories about Darwin’s voyage to the Galapagos Islands or traditional folktales about the different plants and animals.

Logical-quantitative: Examine Darwin’s attempts to map the distributions of the species or pose logical problems about what would happen to the ecosystem if one species disappeared.

Aesthetic: Examine Darwin’s drawings of the species he studied on the Galapagos Islands.

Experiential: Do laboratory activities such as breeding fruit flies or completing virtual simulations of evolutionary processes.

Interpersonal: Form research teams to develop persuasive arguments for those who question the theory of evolution,

Existential/foundational: Consider questions about why species die out or what the purpose is for variation in species.

Multiple Intelligences: Lessons for Teachers

After years of work on his MI theory, Gardner believes two lessons are most important (2009). First, teachers should take the individual differences among students seriously and differentiate their instruction to connect with each student. Much of this book will help you do just that. Second, any discipline, skill, or concept should be taught in several appropriate ways (but not eight ways every time). Anything worth knowing has different representations and multiple connections to various ways of thinking. And understandings can be expressed in words, images, movements, tables, charts, numbers, equations, poetry, and on and on. The MI theory expands our thinking about abilities and avenues for teaching, but learning is still hard work, even if there are multiple paths to knowledge.

Another View: Sternberg’s Successful Intelligence

Robert Sternberg’s **triarchic theory of successful intelligence** is a cognitive processing approach to understanding intelligence that focuses on the skills needed to be successful (Sternberg, 1985, 2004; Sternberg et al., 2014). Sternberg uses the term *successful intelligence* to stress that intelligence is more than what is tested by cognitive abilities measures: Intelligence is about setting and achieving personal goals based on your own definition of success in your particular cultural context. You have to capitalize on your strengths and compensate for weaknesses by selecting tasks and situations (environments) where you can be successful, and then by adapting to or shaping the environment as needed.

Successful intelligence requires three skills or ways of thinking: analytic, creative, and practical. *Analytic skills* involve evaluating, analyzing, judging, comparing, and contrasting to deal with relatively familiar problems. This is the kind of thinking most often taught in school and measured on traditional intelligence tests. *Creative skills* are necessary to cope successfully with new experiences in two ways: (1) using **insight**, or the ability to deal effectively with novel situations and find new solutions, and (2) using **automaticity**, the ability to become efficient and automatic in thinking and problem solving—to quickly make the new solutions part of your cognitive tool kit, so to speak. *Practical skills* focus on choosing an environment in which you can succeed, adapting to that environment, and reshaping it if necessary. Intelligence in this third sense involves practical matters such as career choice or social skills.

How might teachers use Sternberg’s theory to guide instruction and assessment? In a podcast Sternberg gives these examples (Sternberg, 2014).

Triarchic theory of successful intelligence A three-part description of the mental abilities (thinking processes, coping with new experiences, and adapting to context) that lead to more or less intelligent behavior.

Insight In the triarchic theory of intelligence, the ability to deal effectively with novel situations.

Automaticity The ability to perform thoroughly learned tasks without much mental effort. The result of learning to perform a behavior or thinking process so thoroughly that the performance is automatic and does not require effort.

Teaching about World War II

- *Analytic*: Analyze and explain the causes of WWII.
- *Creative*: Imagine and describe what would be different today if Germany had won the war.
- *Practical*: Determine what the events of WWII tell us about how to deal with current world crises today, particularly genocides.

Assessment in Language Arts:

- *Analytic*: Compare and contrast the writing styles of Hemingway and Fitzgerald.
- *Creative*: Write a different ending for *Tom Sawyer*.
- *Practical*: Determine what you can learn from *Tom Sawyer* about persuasion based on the way Tom got his friends to whitewash his fence.

Neuroscience and Intelligence

As you can see, the theories of Spearman, Cattell and Horn, Carroll, Gardner, and Sternberg tend to describe how individuals differ in the *content* of intelligence—different abilities. In contrast, work in cognitive psychology has emphasized the *information processing* that is common to all people. How do humans gather and use information to solve problems and behave intelligently? New views of intelligence are emerging from this work. The debates about intelligence in the 2006 issue of *Behavioral and Brain Sciences* emphasized working memory capacity, the abilities to focus attention and inhibit impulses, and emotional self-regulation as aspects of fluid cognitive abilities. In a study that examined working memory, attention, and speed of information processing, only *working memory* significantly predicted fluid, crystallized, and general intelligence as measured by a common test of adult intelligence (Tourva, Spanoudis, & Demetriou, 2016). We explore these and other aspects of information processing in Chapter 8, so stay tuned.

As you recall, a major feature of the human brain is *plasticity*, changes in neural connections as a result of interactions with the environment. Some neuroscience researchers contend that individual differences in general intelligence are due to differences in neural plasticity—some brains are better than others at forming connections in response to experience. Neural connections develop over childhood to allow for better processing of more and more complex information. Developments in these neural connections that underlie fluid intelligence peak around age 16. So the school years are critical times for development of intellectual abilities (Garlick, 2002). Learning and the development of crystallized intelligence continue throughout life, but experiences in school are particularly important for the growth of fluid abilities. As a teacher, you need to take advantage of the plasticity of your students' brains—they are still developing their intelligence every day.

Even though there are many theories of intelligence, teachers, students, and parents are most familiar with intelligence as a number or score on an intelligence quotient (IQ) test.

Measuring Intelligence

PUT YOURSELF IN THEIR PLACE You are a 9-year-old student being assessed by the school psychologist. She asks you "How are an inch and a mile alike?" "What does *obstreperous* mean?" "Repeat these numbers backwards: 8 5 7 3 0 2 1 9 7." "Here is a completed puzzle. Which three pieces from these possibilities go together to make this puzzle?" •

These items are similar to the questions from a common individual intelligence test for children, the WISC-V (Wechsler, 2014). Another part of the test asks the child to copy a design using blocks, do math problems mentally (without paper and pencil), or select from several pictures the three that were shown earlier, putting them in the same

sequence. Even though psychologists debate about what intelligence is, they do agree that intelligence, as measured by standardized tests, is related to learning in school. Why is this so? It has to do in part with the way intelligence tests were first developed in Paris.

BINET'S DILEMMA. In 1904, Alfred Binet was confronted with the following problem by the minister of public instruction in Paris: How can students who will need special instruction and extra help be identified early in their school careers, before they fail in general education classes? Binet also believed that having an objective measure of learning ability could protect low-income students from being forced to leave school because they were the victims of discrimination and assumed to be slow learners.

Binet and his collaborator Theodore Simon finally identified 58 tests, several for each age group from 3 to 13 that measured the underlying abilities necessary to succeed in school. Binet's tests allowed the examiner to determine a **mental age** for a child. A child who succeeded on the items passed by most 6-year-olds, for example, was considered to have a mental age of 6, whether the child was actually 4, 5, 6, 7, or 8 years old. The concept of **intelligence quotient (IQ)** was added after Binet's test was brought to the United States and revised at Stanford University to give us the Stanford-Binet test. An IQ score was computed by comparing the mental-age score to the person's actual chronological age. The formula was:

$$\text{Intelligence Quotient} = \text{Mental Age} / \text{Chronological Age} \times 100$$

The early Stanford-Binet test has been revised five times, most recently in 2003 (Roid, 2003). Today we don't use mental age, but instead compute a **deviation IQ**—a number that tells exactly how much a person's score is above or below the average for her or his age group.

WHAT DOES AN IQ SCORE MEAN? Most intelligence tests such as the Stanford-Binet and the WISC-V are designed so that they have certain statistical characteristics. For example, the average score is 100; 50% of the people from the general population who take the tests will score 100 or below, and 50% will score above 100. About 68% of the general population will earn IQ scores between 85 and 115. Only about 16% will receive scores below 85, and only 16% will score above 115. Note, however, that these figures hold true for White, native-born Americans whose first language is Standard English. Whether IQ tests should even be used with ethnic minority-group students is hotly debated.

GROUP VERSUS INDIVIDUAL IQ TESTS. The Stanford-Binet and the WISC-V are individual intelligence tests. They have to be administered to one student at a time by a trained psychologist, and take about 1 to 2 hours. Most of the questions are asked orally and do not require reading or writing. A student usually pays closer attention and is more motivated to do well when working directly with an adult.

Psychologists also have developed group tests that can be given to whole classes or schools. Compared to an individual test, a group test is much less likely to yield an accurate picture of any one person's abilities. When students take tests in a group, they may do poorly for many reasons: they do not understand the instructions, they have trouble reading, their pencils break or they lose their place on the answer sheet, other students distract them, or the answer format confuses them (Sattler, 2008). As a teacher, you should be *very wary* of IQ scores based on group tests. The *Guidelines: Interpreting IQ Scores* will help you interpret IQ scores realistically.

THE FLYNN EFFECT: ARE WE GETTING SMARTER? Ever since IQ tests were introduced in the early 1900s, scores in 20 different industrialized countries and in some more traditional cultures have been rising. In fact, in a decade, the average score goes up about 3 points on standardized IQ tests; this is called the **Flynn effect** after James Flynn, a political scientist who documented the phenomenon (Daley, Whaley, Sigman, Espinosa, & Neumann, 2003; Folger, 2012). So are you smarter than your parents? James Flynn (2012) answers this way:

Connect and Extend to PRAXIS II®

Intelligence Testing (II, C1, 4)

The public often misunderstands intelligence testing. Be prepared to respond to questions about the appropriate uses of intelligence tests. What are some inappropriate uses of these tests?

Mental age In intelligence testing, a performance that represents average abilities for that age group.

Intelligence quotient (IQ) Score comparing mental and chronological ages.

Deviation IQ Score based on a statistical comparison of an individual's performance with the average performance of others in that age group.

Flynn effect Because of better health, smaller families, increased complexity in the environment, and more and better schooling, IQ test scores are steadily rising.

GUIDELINES

Interpreting IQ Scores

Check to see if the score is based on an individual or a group test. Be wary of group test scores.

Examples

1. Individual tests include the Wechsler Scales (WPPSI-IV, WISC-V, WAIS-IV), the Stanford-Binet, the Woodcock-Johnson Psycho-Educational Battery, the Naglieri Nonverbal Ability Test—Individual, and the Kaufman Assessment Battery for Children (2nd Edition).
2. Group tests include the Otis-Lennon School Abilities Tests (8th edition), Slosson Intelligence Test (R3), Raven Progressive Matrices, Naglieri Nonverbal Ability Test (2nd edition, online), Differential Abilities Scales II, and Wide Range Intelligence Test.

Remember that IQ tests are only estimates of general aptitude for learning.

Examples

1. Ignore small differences in scores among students.
2. Bear in mind that even an individual student's scores may change over time for many reasons, including development of new abilities or measurement error.

3. Be aware that a total score is usually an average of scores on several kinds of questions. A score in the middle or average range may mean that the student performed at the average on every kind of question or that the student did quite well in some areas (e.g., on verbal tasks) and rather poorly in other areas (e.g., on spatial tasks).

Remember that IQ scores reflect a student's past experiences and learning.

Examples

1. Consider these scores to be predictors of school abilities, not measures of innate intellectual abilities.
2. If a student is doing well in your class, do not change your opinion or lower your expectations just because one score seems low—there are many reasons for low scores.
3. Be wary of IQ scores for minority students and for students whose first language is not English. Even scores on "culture-free" tests are lower for students placed at risk.

If you mean "Do our brains have more potential at conception than those of our ancestors?" then we are not. If you mean "Are we developing mental abilities that allow us to better deal with the complexity of the modern world, including problems of economic development?" then we are. (p. 1)

Some explanations for the Flynn effect include better nutrition and medical care for children and parents, increasing complexity in the environment that stimulates abstract thinking, smaller families who give more attention to their children, increased literacy of parents (particularly better-educated mothers), more and better schooling, and better preparation for taking tests.

INTELLIGENCE AND ACHIEVEMENT. Scoring higher on IQ tests is related to academic achievement for children in all ethnic groups (Cucina, Peyton, Su, & Byle, 2016). In fact, researchers following 14,000 British children in the *Avon Longitudinal Study of Parents and Children* found a clear relationship ($r=.64$) between measured IQ at age 8 and achievement on standardized tests in math, English, and science at age 14. But beware of overinterpreting this relationship. Statistically, this correlation means that IQ explains less than 41% of the variation in achievement. Almost 60% is related to other factors (Bornstein, Hahn, & Wolke, 2013).

The relations between IQ scores and school achievement are interesting, but standard IQ tests measure only *analytic* skills, not *practical* or *creative* thinking, or motivation. Angela Duckworth and her colleagues (2012) found that IQ scores predict standardized test scores, but that measures of self-regulation (see Chapter 11) are better predictors of grades in school. So IQ test scores are related to some kinds of academic achievement, but if measures of self-regulated learning skills, practical intelligence, and creativity are included, we can make even better predictions of school success (Grigorenko, 2009).

But what about life after school? Do people who score high on IQ tests achieve more in life? Here the answer is less clear, because life success and education are intertwined.

High school graduates earn about \$678 per week and have a 5.4% unemployment rate. College graduates earn about \$1,137 per week with a 2.8% unemployment rate, and people with professional degrees such as in law or medicine earn around \$1,730 per week with a 1.5% unemployment rate (Bureau of Labor Statistics, 2016). People with higher intelligence test scores tend to complete more years of school. However, when the number of years of education is held constant, the correlation decreases between IQ scores, income, and success in later life. Other factors such as self-regulation, motivation, creativity, common sense, social skills, and luck may make the difference in life achievement (Alarcon & Edwards, 2013; Neisser et al., 1996).

Gender Differences in Intelligence and Achievement

From infancy through the preschool years, most studies find few differences between boys and girls in overall mental and motor development or in specific abilities. But, during the school years and beyond, scores on some tests of specific abilities do show sex differences. Also, the scores of males tend to be slightly more variable in general, so there are more males than females with very high and very low scores on tests (Baye & Monseur, 2016; Lindberg, Hyde, Peterson, & Linn, 2010). In addition, more boys than girls are diagnosed with learning disabilities, ADHD, and autism. Diane Halpern and her colleagues (2007) summarize the research:

By the end of grade school and beyond, females perform better on assessments of verbal abilities when assessments are heavily weighted with writing and the language-usage items cover topics with which females are familiar; sex differences favoring females are much larger in these conditions than when assessments of verbal abilities do not include writing. In contrast, males excel on certain visuospatial-ability measures. (p. 40)

There are two cautions, however. These sex differences generally are small. Also, in most studies, race and ethnicity are not taken into account.

Several recent international assessments have found some sex differences in *academic achievement* (not specific intellectual abilities). For example, the results of the 2012 PISA tests of 15-year-olds showed that girls outperformed boys in all 65 countries in *reading literacy*. The United States gap of 31 points seemed large, but in Finland, girls outperformed boys by 62 points (Loveless, 2015). But between 2009 and 2015, this gap between boys and girls had narrowed by 12 points on average across all the countries assessed (OECD, 2016). Other international studies have found few differences in *mathematics* achievement for boys and girls. For example, analysis of data from 242 studies that included over a million elementary through high school students found that girls' and boys' performance in mathematics is comparable in some nations including the United States, but girls scored higher than boys in several countries such as Russia, Bahrain, and Mexico, while boys' scores were higher in other countries such as Switzerland, the Netherlands, and African nations (Else-Quest, Hyde, & Linn, 2010; Lindberg et al., 2010).

Recently, the National Assessment of Educational Progress (NAEP) added an assessment of Technology and Engineering Literacy to its battery of tests. On the first administration, eighth-grade girls in the United States outperformed boys (NAEP, 2016). Armed with such information from the NAEP assessments and the results of international tests, parents, teachers, guidance counselors, and students can challenge the stereotypes about female inferiority in math and technology.

HEREDITY OR ENVIRONMENT? Nowhere has the nature-versus-nurture debate raged so hard as in the area of intelligence. Should intelligence be seen as a potential, limited by our genetic makeup? Or does intelligence simply refer to an individual's current level of intellectual functioning, as influenced by experience and education?

Beware of either/or comparisons: It is impossible to separate intelligence "in the genes" from intelligence "due to experience." Today, most psychologists believe that differences in intelligence are the result of both heredity and environment, probably in about equal proportions for children (Petrill & Wilkerson, 2000). And environmental influences include everything from the health of a child's mother during pregnancy to

the amount of lead in the child's home to the quality of teaching a child receives. For example, when German secondary school students participated in an academic track (a high-quality and demanding learning environment) rather than a vocational track in school, their general cognitive abilities (intelligence) improved (Becker, Lüdtke, Trautwein, Köller, & Baumert, 2012).

Learning to Be Intelligent: Being Smart About IQ

We saw that intelligence tests originally were developed, in part, to protect the rights of low-income children who might have been denied an education on the false grounds that they weren't able to learn. Even so, these tests can never be free of cultural content, so they always will have some biases built in. Keep this in mind when you see your students' scores on any test. Finally, remember that the results of every assessment for every student should be used to support that student's learning and development and to identify effective practices, not to deny the student access to resources or appropriate teaching. For all adults caring for children—parents, teachers, administrators, counselors, medical workers—it is especially important to realize that cognitive skills, like any other skills, can always be improved. *Intelligence is a current state of affairs, affected by past experiences and open to future changes.* Remember, brain plasticity through childhood and adolescence makes the school years especially important in developing intellectual skills (Garlick, 2002).

You saw above that some explanations of intelligence include creativity—let's take a deeper look.

MyLab Education Self-Check 4.1

CREATIVITY: WHAT IT IS AND WHY IT MATTERS

PUT YOURSELF IN HIS PLACE Consider this student. He had severe dyslexia—a learning disability that made reading and writing exceedingly difficult. He described himself as an “underdog.” In school, he knew that if the reading assignment would take others an hour, he had to allow 2 or 3 hours. He knew that he had to keep a list of all of his most frequently misspelled words to be able to write at all. He spent hours alone in his room. Would you expect his writing to be creative? Why or why not? •

The person described in this *Put Yourself in His Place* is John Irving, celebrated author of what one critic called “wildly inventive” novels such as *The World According to Garp*, *The Cider House Rules*, and *A Prayer for Owen Meany* (Amabile, 2001). How do we explain his amazing creativity? What is creativity?

Generally, definitions of **creativity** include two elements: novelty/originality and high quality/effectiveness/usefulness (Henriksen & Mishra, 2015; Plucker, Beghetto, & Dow, 2004). Most psychologists agree that there is no such thing as “all-purpose creativity”; people are creative in a particular area, as John Irving was in writing fiction. To be creative in a particular domain requires a deep understanding of the subject, so we can view creativity as a process that uses existing knowledge and also improvises and invents to produce something new (Sawyer, 2015). A Teacher of the Year said it this way: “Creativity means to use your background knowledge. . . . Taking something that already exists and putting your own spin on it” (Henriksen & Mishra, 2015, p. 10). Also, to be creative, the “invention” must be intended. An accidental spilling of paint that produces a novel design is not creative unless the artist recognizes the potential of the “accident” or uses the spilling technique intentionally to create new works (Weisberg, 1993). Although we frequently associate the arts with creativity, any subject can be approached in a creative

Creativity Imaginative, original thinking or problem solving.

manner. The Teachers of the Year interviewed by Henriksen and Mishra (2015) stressed that *creativity can be learned*. It is a habit of mind that involves nurturing enthusiasm and being open to new ideas.

Assessing Creativity

STOP & THINK How many uses can you list for a brick? Take a moment and brainstorm—write down as many as you can. •

Like the author John Irving, Paul Torrance had a learning disability. He became interested in educational psychology when he was a high school English teacher (Neumeister & Cramond, 2004). Torrance was known as the “Father of Creativity.” He developed two types of creativity tests: verbal and graphic (Torrance, 1972, 2008; Torrance & Safter, 1986). In the verbal test, you might be instructed to think up as many uses as possible for a brick (as you did above) or asked how a particular toy might be changed to make it more fun. On the graphic test, you might be given 30 circles and asked to create 30 different drawings, with each drawing including at least one circle. Figure 4.2 shows the creativity of an 8-year-old girl in completing this task.

FIGURE 4.2

A GRAPHIC ASSESSMENT OF THE CREATIVITY OF AN EIGHT-YEAR-OLD

The titles she gave her drawings, from left to right, are as follows: “Dracula,” “one-eyed monster,” “pumpkin,” “Hula-Hoop,” “poster,” “wheelchair,” “earth,” “moon,” “planet,” “movie camera,” “sad face,” “picture,” “stoplight,” “beach ball,” “the letter O,” “car,” “glasses.”

Source: “A Graphic Assessment of the Creativity of an Eight-Year-Old,” from *The Torrance Test of Creative Thinking* by E. P. Torrance, 1986, 2000. Reprinted with permission of Scholastic Testing Service, Inc., Bensonville, IL 60106 USA.

These creativity tests require divergent thinking, an important component of many conceptions of creativity. **Divergent thinking** is the ability to propose many different ideas or answers. **Convergent thinking** is the more common ability to identify only one answer. Divergent thinking has three aspects: originality, fluency, and flexibility. *Originality* is usually determined statistically. To be original, a response must be given by fewer than 5 or 10 people out of every 100 who take the test. *Fluency* is the sheer number of different responses. *Flexibility* is generally measured by the number of different categories of responses. For instance, if you listed 20 uses of a brick, but each was to build something, your fluency score might be high (high number of uses), but your flexibility score would be low (just one category of use). Of the three measures, fluency—the sheer number of responses—is the best predictor of divergent thinking, but there is more to real-life creativity than divergent thinking (Plucker et al., 2004).

A few possible indicators of creativity in your students are curiosity, concentration, adaptability, high energy, humor (sometimes bizarre), independence, playfulness, risk taking, attraction to the complex and mysterious, seeing different perspectives, nonconformity, willingness to fantasize and daydream, intolerance for boredom, and inventiveness (Sattler & Hoge, 2006; Swayer, 2015).

OK, But So What: Why Does Creativity Matter?

I cannot read any news these days without feeling depressed about the problems facing the world. Economic problems, health problems, energy problems, political problems, violence, poverty, civil and religious wars, the list goes on. Certainly today's and tomorrow's complex problems will require creative solutions. "Creativity is one of the most important skills needed in the 21st century" (Sawyer, 2015, p. 2). And creativity is important for an individual's psychological, physical, social, and career success (Henriksen & Mishra, 2015). In addition, evidence shows that creativity and critical thinking are needed to prevent people or societies from being trapped by ideology and dogma (Ambrose & Sternberg, 2012; Plucker et al., 2004). Alene Starko (2014) described her visit to China, where educators all over that country kept asking her how to help their students become more creative, flexible thinkers. These Chinese students knock the top off of the international tests, but their focus on mastering academics comes at a cost to their creativity and critical thinking. In fact, many teachers will tell you that the pressures of accountability and preparing their students for high-stakes tests have forced creative teaching and teaching for student creativity out of the classroom (Noddings, 2013).

But we don't have to choose between understanding and creativity. Strategies that support creativity also support deep understanding in school subjects, because deep understanding comes from using the content in multiple ways and seeing different implications of that knowledge—"putting your own spin on it." Creativity also supports intrinsic motivation, engagement, and persistence in learning because creativity generates novelty and sparks interest (Starko, 2014).

What Are the Sources of Creativity?

Researchers have studied cognitive processes, personality factors, motivational patterns, and background experiences to explain creativity (Simonton, 2000). Teresa Amabile (1996, 2001) proposed a three-component model of creativity. Individuals or groups must have:

1. *Domain-relevant skills* including talents and competencies that are valuable for working in the domain, such as Michelangelo's skills in shaping stone, developed when he lived with a stonecutter's family as a child.
2. *Creativity-relevant processes* including work habits and personality traits such as John Irving's habit of working 10-hour days to write and rewrite and rewrite until he perfected his stories.

Divergent thinking Coming up with many possible solutions.

Convergent thinking Narrowing possibilities to a single answer.

3. *Intrinsic task motivation* or a deep curiosity and fascination with the task. This aspect of creativity can be greatly influenced by teachers who support autonomy, stimulate curiosity, encourage fantasy, and provide challenge.

CREATIVITY AND COGNITION. Having a rich store of knowledge in an area is the basis for creativity, but something more is needed. For many problems, that “something more” is the ability to see things in a new way—**restructuring** the problem, which leads to a sudden *insight*. Often this happens when a person has struggled with a problem or project and then sets it aside for a while. Some psychologists believe that time away allows for *incubation*, a kind of unconscious working through the problem. Actually, it is more complex than that. Incubation is more helpful when a longer preparation period precedes the individual’s setting the problem aside (Sio & Ormerod, 2009). Leaving the problem for a time probably interrupts rigid ways of thinking so you can restructure your view of the situation and think more divergently (Gleitman, Fridlund, & Reisberg, 1999). Creativity requires extensive knowledge, flexibility, and the continual reorganizing of ideas as well as motivation and persistence.

CREATIVITY AND DIVERSITY. As Dean Simonton said, even with years of research on creativity, “Psychologists still have a long way to go before they come anywhere close to understanding creativity in women and minorities” (2000, p. 156). Thus far, white males have been the focus of creativity research and writing over the years. However, patterns of creativity in other groups are complex—sometimes matching and sometimes diverging from patterns found in traditional research.

In another connection between creativity and culture, research suggests that being on the outside of mainstream society, being bilingual, or being exposed to other cultures might encourage creativity (Simonton, 2000). In fact, true innovators often break rules. “Creators have a desire to shake things up” (Winner, 2000, p. 167). And even for those who are not outside the mainstream, participation in multicultural experiences apparently supports retrieving novel or unconventional ideas from memory and creative performance, such as generating insightful solutions to problems. These effects are especially strong when people open themselves up to divergent ideas and when the situation does not emphasize finding quick, firm answers. Multicultural individuals are particularly willing to consider and build on unfamiliar ideas, entertain conflicting alternatives, and make unlikely connections between ideas (Leung & Chiu, 2010; Maddux & Galinsky, 2009). So even though your students may not be able to travel to Tibet or Tonga, they still could become more creative problem solvers if they learned about different cultures.

Creativity in the Classroom

STOP & THINK Consider these two students described by Alane Starko (2014, p. 3):

In first grade, Michelle was given an outline of a giant shark’s mouth on a worksheet that asked, “What will our fishy friend eat next?” She dutifully colored several fish and boats, and then wrote the following explanation: “Once there was a shark named Peppy. One day he ate three fish, one jellyfish, and two boats. Before he ate the jellyfish, he made a peanut butter and jellyfish sandwich.”

At 19, Juan was homeless and a senior in high school. One cold evening he thought that a warm space inside the school would be a more appealing sleeping place than any he could see. Getting into the building was no problem, but once he was inside a motion detector would make him immediately detectable to the guard on the floor below. Juan entered a storage room and carefully dislodged a pile of baseball bats. In the ensuing commotion, he located a comfortable sleeping place. The guard attributed the motion detector’s outburst to the falling bats, and Juan slept until morning. •

Restructuring Conceiving of a problem in a new or different way.

Are these students creative? What might teachers do to foster or to inhibit creative thinking? All too often, in the crush of day-to-day classroom life, teachers stifle creative ideas without realizing what they are doing. Teachers are in an excellent position to encourage or discourage creativity through their acceptance or rejection of the unusual and imaginative.

BRAINSTORMING. The basic tenet of **brainstorming** is to separate the process of creating ideas from the process of evaluating them because evaluation often inhibits creativity (Osborn, 1963). Evaluation, discussion, and criticism are postponed until all possible suggestions have been made. In this way, one idea inspires others; people do not withhold potentially creative solutions out of fear of criticism. Alene Starko (2014) gives these rules for brainstorming:

1. No criticism of any ideas until all the ideas are on the table. This includes both verbal and nonverbal criticism, so no eye-rolling or laughing.
2. Go for as many ideas as you can. Quantity may lead to quality as one idea inspires another.
3. Feel free to “hitchhike” on other ideas. This means that it’s okay to borrow elements from ideas already on the table, or to make slight modifications of ideas already suggested.
4. Encourage wild ideas. Impossible, totally unworkable ideas may lead someone to think of other, more possible, more workable ideas. It’s easier to take a wildly imaginative bad idea and tone it down to fit the constraints of reality than it is to take a boring bad idea and make it interesting enough to be worth thinking about.

Individuals as well as groups may benefit from brainstorming. In writing this book, for example, I have sometimes found it helpful to list all the different topics that could be covered in a chapter, then leave the list and return to it later to evaluate the ideas.

The *Guidelines: Applying and Encouraging Creativity* on the next page adapted from Fleith (2000), Sawyer (2015), and Sattler and Hoge (2006), describe other possibilities for encouraging creativity.

In applying these Guidelines, remember that students need a solid base of knowledge to support the creative process. Creativity is a balance between structure and improvisation.

CREATIVE SCHOOLS. Keith Sawyer (2015) summarizes teaching for creativity and teaching creatively by describing creative schools. In these schools students learn content knowledge, not in superficial memorized ways but instead with a deep understanding that prepares them to go beyond, improvise, and invent. Students also learn collaboratively, which encourages them to express, explain, and test their developing understandings, so they learn how to think about their own thinking—called *metacognition*, as you will see in Chapter 9. As a result, the students:

learn to participate in creative activities based on their developing knowledge—how to identify good problems, how to ask good questions, how to gather relevant information, how to propose new solutions and hypotheses, and how to use domain-specific skills to express those ideas and make them a reality. The school of the future will be filled with creative learning environments that result in deeper mastery of content knowledge, and the ability to think and act creatively using that knowledge. (Sawyer, 2015, p. 18).

We turn now to a claim about individual differences that is really controversial—learning styles.

Brainstorming Generating ideas without stopping to evaluate them.

GUIDELINES

Applying and Encouraging Creativity

Accept and encourage divergent thinking.

Examples

1. During class discussion, ask: "Can anyone suggest a different way of looking at this question?"
2. Reinforce attempts at unusual solutions to problems, even if the final product is not perfect.
3. Offer choices in topics for projects or modes of presentation (written, oral, visual or graphic, using technology).

Tolerate dissent and question assumptions.

Examples

1. Ask students to support dissenting opinions.
2. Make sure nonconforming students receive an equal share of classroom privileges and rewards—allow students to be eccentric.
3. Identify and examine unstated assumptions—Where are we starting? What is the real problem?

Encourage students to take reasonable risks and trust their own judgment.

Examples

1. When students ask questions you think they can answer, rephrase or clarify the questions and direct them back to the students.
2. Give ungraded assignments from time to time.
3. Celebrate mistakes as opportunities to dig deeper and learn.
4. Take risks in your own teaching. Model how to learn from successes or failures of risk taking.

Emphasize that everyone is capable of creativity in some form.

Examples

1. Avoid describing the feats of great artists or inventors as if they were superhuman accomplishments.
2. Recognize creative efforts in each student's work. Have a separate grade for originality on some assignments.

Provide time, space, collaborative partners, and materials to support creative projects.

Examples

1. Collect "found" materials for collages and creations—buttons, stones, shells, paper, fabric, beads, seeds, drawing tools, clay—try flea markets and friends for donations. Have mirrors and pictures for drawing faces.
2. Tie learning to real world problems—for example, have student groups create nonprofit organizations to

address a real community problem, write a grant to fund a solution, and then present their ideas to a panel of community members who will choose the most persuasive project (Henriksen & Mishra, 2015).

3. Follow up on memorable occasions (field trips, news events, holidays) with opportunities to draw, write, or make music.
4. Encourage students to tackle problems in small groups.

Take your time and play.

Examples

1. Encourage and celebrate fantasy, humor, absurdity, and quirkiness.
2. Play with ideas, what-ifs, materials, melodies, words, movement, puzzles—whatever fits your subject matter.

Be a stimulus for creative thinking.

Examples

1. Use class brainstorming sessions whenever possible. Encourage students to delay judging a particular suggestion for solving a problem until all the possibilities have been considered.
2. Model creative problem solving by suggesting unusual solutions for class problems.
3. Share your own interests and passions in music, art, films, geology, history, crafts, cooking, sports, travel, archeology, languages, fiction, theater etc. in your teaching.

Capitalize on technology (Starko, 2014).

Examples

1. Have students use free apps such as Spider Scribe (spiderscribe.net) to create visual maps of ideas and share their ideas with others.
2. Spend the five minutes before lunch or at the end of class creatively by having students practice divergent thinking using Genius on the Go on their iPhone, iPod, or iPad.
3. Encourage students to create a Facebook page for a literary or historical figure using Fakebook from Classtools.net. Go to classtools.net/FB/home-page.
4. Use Wordle (wordle.net), WordCloud (wordcloud.com), or tagxedo (tagxedo.com) to create word clouds showing the frequency of words used in a particular text or the student's writing. See Figure 4.3 for a word cloud of this chapter made with WordCloud.

For more ideas, see ecap.crc.illinois.edu and search for "creativity."

FIGURE 4.3

A WORD CLOUD OF THIS CHAPTER

In this word cloud, the frequency of the words in this chapter is indicated by the size of the word, so you can see that “may,” “student,” “children,” and “can” appear most often.

LEARNING STYLES

For many years, researchers have examined individual differences in “styles”—cognitive styles, learning styles, problem-solving styles, thinking styles, decision-making styles . . . the list goes on. The one you will hear most about as a teacher is learning styles—proceed with caution!

Learning Styles/Preferences

Do you think you have a particular learning style? **Learning style** usually is defined as the way a person approaches learning and studying. But beware—*some conceptions of learning styles have little research support*; others are based on solid studies. First, the cautions.

CAUTIONS ABOUT LEARNING STYLES. Even though you will hear the term “learning styles” constantly, I believe **learning preferences** is a more accurate label because most of the research describes *preferences* for particular learning environments—for example, where, when, with whom, or with what materials, lighting, food, or music you like to study. A number of instruments assess students’ learning preferences, including The Learning Style Inventory (Dunn, Dunn, & Price, 1989), Learning Styles Inventory (Revised) (McLeod, 2010), and the Learning Style Profile (Keefe & Monk, 1986).

Are these useful tools? Tests of learning style have been strongly criticized (Pashler, McDaniel, Rohrer, & Bjork, 2009). In fact, in an extensive examination of learning styles instruments, researchers at the Learning Skills Research Centre in England concluded, “with regard to work by Dunn and Dunn, Gregorc, and Riding, our examination of the reliability and validity of their learning style instruments strongly suggests that they should not be used in education or business” (Coffield et al., 2004, p. 127), in part because matching instructional methods to learning styles has no effect on learning (Stahl, 2002).

Two experimental studies demonstrate the problems with teaching to particular learning styles. In the first, college students self-assessed their learning style as auditory, visual, or kinesthetic and then were taught in keeping with their professed style. Matching learning style with teaching method *did not* improve learning (Kratzig & Arbuthnott, 2006). When the researchers examined how people identified their own learning styles, they concluded that people’s judgments represented preferences rather than superior

Connect and Extend to PRAXIS II®

Learning/Cognitive Styles (I, B1)

Familiarize yourself with the major issues involved with learning and cognitive styles, and understand their implications for classroom practice.

Learning styles Characteristic approaches to learning and studying.

Learning preferences Preferred ways of studying and learning, such as using pictures instead of text, working with other people versus alone, learning in structured or in unstructured situations, and so on.

skills in using auditory, visual, or kinesthetic modalities. If college students have trouble identifying their own learning style, think about fourth or ninth graders! In the second study (Rogowsky, Calhoun, & Tallal, 2015), college students completed the *Building Excellence Online Learning Styles Assessment Inventory* for age 17 and older (Rundle & Dunn, 2010) to determine if they had auditory or visual word learning styles. Then the participants were randomly assigned to instruction from a nonfiction book that either used an audiobook version or an e-text. Again, matching learning style to mode of instruction had *no effect on comprehension*. In summary, liking to learn a particular way does not lead to better learning. “[Y]ou learn better when you ‘go wide,’ drawing on all of your aptitudes and resourcefulness, than when you limit instruction or experience to the style you find most amenable” (Brown, Roediger, & McDaniel, 2014. p. 4).

So why are these ideas so popular? Part of the answer is that many thriving commercial companies are making large profits by providing advice to teachers, tutors, and managers about learning styles based on “inflated claims and sweeping conclusions” (Coffield et al., 2004, p. 127). Money talks. Also, the idea of multimodal learning is popular. People like visual materials and animated presentations. But these animations can lead to a phenomenon called an *illusion of understanding*. Students think they understand because the content seems less difficult; they become overly optimistic and then they don’t monitor their learning or use other metacognitive skills to process deeply. Lower-ability learners are especially susceptible to developing illusions of understanding with animated presentations (Paik & Schraw, 2013).

THE VALUE OF CONSIDERING LEARNING STYLES. There is one learning styles distinction that has research support. Richard Mayer (e.g., Mayer, 2009; Mayer & Massa, 2003) has been studying the distinction between visual and verbal learners, with a focus on learning from computer-based multimedia. Here, the assessment of learning styles is carefully done and more valid than assessments based on many of the commercial inventories. Mayer has found a visualizer–verbalizer dimension that has three facets: *cognitive spatial ability* (low or high), *cognitive style* (visualizer vs. verbalizer), and *learning preference* (visual learner vs. verbal learner), as shown in Table 4.2. So the picture is more complex than simply being a visual or a verbal learner. A student might have a preference for learning with pictures, but low spatial ability could make using pictures for learning less effective. To complicate matters even more, spatial abilities may be important for learning from static pictures but less important for learning from animation; so the type of learning materials matters, too (Hoeffler & Leutner, 2011). These differences can be reliably measured, but research has not identified the effects of teaching to these styles; certainly, presenting information in multiple modalities might be useful.

TABLE 4.2 • Richard Mayer’s Three Facets of the Visualizer–Verbalizer Dimension

There are three facets to visual versus verbal learning: ability, style, and preference. Individuals can be high or low on any or all of these facets.

FACET	TYPES OF LEARNERS	DEFINITION
Cognitive Ability	High spatial ability	Good abilities to create, remember, and manipulate images and spatial information
	Low spatial ability	Poor abilities to create, remember, and manipulate images and spatial information
Cognitive Style	Visualizer	Thinks using images and visual information
	Verbalizer	Thinks using words and verbal information
Learning Preference	Visual learner	Prefers instruction using pictures
	Verbal learner	Prefers instruction using words

So before you try to accommodate all your students' learning styles, remember that students, especially younger ones, may not be the best judges of how they should learn. Preference for a particular style does not guarantee that using the style will be effective. Sometimes students, particularly students who struggle, prefer what is easy and comfortable (e.g., animation to explain difficult material); real learning can be hard and uncomfortable. In some cases, students prefer to learn in a certain way because they have no alternatives; it is the only way they know how to approach the task. These students may benefit from developing new—and perhaps more effective—ways to learn.

Beyond Either/Or

Even though much of the work on matching learning styles and preferences to teaching is suspect, with unreliable measures and inflated claims, thinking about learning styles has some value. First, by helping students think about how they learn, you can develop thoughtful self-monitoring and self-awareness. Second, looking at individual students' approaches to learning might help teachers appreciate, accept, and accommodate student differences and differentiate instruction (Coffield et al., 2004; Rosenfeld & Rosenfeld, 2004).

Schools can make more learning options available, such as having quiet, private corners as well as large tables for working; comfortable cushions as well as straight chairs; brightly lighted desks along with darker areas; headphones for listening to music as well as earplugs; structured as well as open-ended assignments; and information available from visuals, podcasts, Web sites, and DVDs as well as books. Will making these modifications lead to greater learning? Here the answer is not clear. Very bright students appear to need less structure and to prefer quiet, solitary learning (Torrance, 1986), and Mayer's visual-verbal distinction seems to be valid, but complicated to use. If nothing else, some accommodation of student preferences may make your classroom more inviting and student friendly and communicate to your students that you care about them as individuals.

Thus far, we have focused mostly on the varying abilities and styles of students. For the rest of the chapter, we will consider factors that can interfere with learning. It is important for all teachers to be aware of these issues because laws and policy changes initiated in the mid-1970s continue to expand teachers' responsibilities in working with all students.

MyLab Education Self-Check 4.3

INDIVIDUAL DIFFERENCES AND THE LAW

PUT YOURSELF IN THEIR PLACE Have you ever had the experience of being the only one in a group who had trouble doing something? How would you feel if every day in school you faced the same kind of difficulty, while everyone else seemed to find the work easier than you? What kind of support and instruction would you need to keep on trying and not give up? •

IDEA

Since 1975, in the United States, a series of laws, beginning with PL 94–142 (now called the **Individuals with Disabilities Education Act**, or **IDEA**), has led to revolutionary changes in the education of children with disabilities. IDEA was last revised in 2004. At the most general level, the law now requires states to provide a **free, appropriate public education (FAPE)** for all students with disabilities who participate in special education. There are no exceptions—the law requires **zero reject**. This policy also applies to students with communicable diseases such as AIDS. The expenses of meeting the special needs of these students are considered a public responsibility. Every state in the United States has a *child find* system to alert and educate the public about services for children with disabilities and to distribute useful information. As I am writing this section, I am aware that there could be major changes in these laws with the current administration. Stay tuned and keep up with the requirements in your state.

Individuals with Disabilities Education Act (IDEA) Latest amendment of PL 94–142; guarantees a free public education to all children regardless of disability.

Free, appropriate public education (FAPE) Public funding to support appropriate educational programs for all students, no matter what their needs.

Zero reject A basic principle of the Individuals with Disabilities Education Act specifying that no student with a disability, no matter what kind or how severe, can be denied a free public education.

MyLab Education Video Example 4.2

In this IEP conference, the parent describes the development of her daughter's individualized education program, and the team members discuss her current goals. How do the parents and the child benefit from participation in this type of meeting?

Least restrictive environment (LRE)

Educating each child with peers in the general education classroom to the greatest extent possible.

Mainstreaming Teaching children with disabilities in regular classes for part or all of their school day.

Integration Fitting the child with special needs into existing class structures.

Inclusion The integration of all students, including those with severe disabilities, into regular classes.

Individualized education program (IEP) Annually revised program for an exceptional student, detailing present achievement level, goals, and strategies, drawn up by teachers, parents, specialists, and (if possible) the student.

The definition of *disability* is specific in IDEA. The 13 categories of disabilities covered are listed in Table 4.3, along with the numbers of students in each category. In 2013, just over 80% of these students received at least 40% of their instruction in general education settings (Center for Public Education, 2014). You can see that no matter what grade or subject you teach, you will work with students with special needs.

Before we look at the different categories, let's examine the requirements in IDEA. Three major points are of interest to parents and teachers: the concept of "least restrictive placement"; the individualized education program; and the protection of the rights of both students with disabilities and their parents.

LEAST RESTRICTIVE ENVIRONMENT. IDEA requires states to develop procedures for educating each child in the **least restrictive environment (LRE)**, a setting that is as close to the general education class setting as possible. Over the years, recommended approaches to achieve this have moved from **mainstreaming** (including children with special needs in a few general education classes as convenient), to **integration** (fitting the child into existing class structures), to **inclusion** (restructuring educational settings to promote belonging for all students) (Avramidis, Bayliss, & Burden, 2000; Scruggs & Mastropieri, 2013). Even though the IDEA legislation does not use the word *inclusion*, today the LRE is assumed to be inclusion as much as possible. However, an emphasis on standardized testing may interfere with good teaching for included students (Friend & Bursuck, 2019; Idol, 2006; Kemp & Carter, 2006).

INDIVIDUALIZED EDUCATION PROGRAM. The drafters of the laws recognized that each student is unique and may need a specially tailored program to make progress. The **Individualized Education Program (IEP)** is an agreement between parents and the school

TABLE 4.3 • Students Ages 3 to 21 Served Under IDEA

Thirteen categories of students are served under IDEA. The table shows the number of students in each category in the Fall 2014 school year. (nces.ed.gov)

DISABILITY	NUMBER OF STUDENTS IN 2014–2015
Specific learning disabilities	2,278,000
Speech/language impairments	1,332,000
Other health impairments (not orthopedic)	862,000
Autism spectrum disorders	576,000
Intellectual disability	423,000
Developmental delay	419,000
Emotional disturbances	349,000
Multiple disabilities	132,000
Hearing impairments	76,000
Orthopedic impairments	52,000
Visual impairments	28,000
Traumatic brain injury	26,000
Deaf-blind	1,000
Total	6,555,000

about the services that will be provided to the student. The IEP is written by a team that includes the student's parents or guardians, a general education teacher who works with the student, a special education teacher, a representative of the school district (often the principal), a qualified person who can interpret the student's evaluation results (often a school psychologist), and (if appropriate) the student. For students 16 and older, the team may include representatives from outside agencies who are providing services to help the student make transitions to life and support services after school. If the school and parents or guardians agree, the team could add other people who have special knowledge of the child (e.g., a therapist). The program usually is updated each year.

The IEP must state in writing:

1. The student's *present level of academic achievement and functional performance* (sometimes referred to as *PLAAFP*, or just *PLOP*—present level of performance). This can include social skills, behavior, communication skills, and any other areas of concern.
2. *Annual goals*—measurable performance goals for the year in academic and/or non-academic areas, depending on the student's strengths and weaknesses. Students with significant needs or multiple disabilities may also have *short-term objectives*, or *benchmarks*, to make sure progress is continuous. Goals should enable the student to access the general education curriculum.
3. The plan must tell *how progress toward these goals and objectives will be measured*. Parents must get progress reports at least as often as report cards are sent home for all students.
4. A statement of *specific special education and related services* to be provided to the student and details of when and where those services will be initiated and when they will end. This statement can include descriptions of supplementary aids and assistive technologies (e.g., using speech recognition software such as *Dragon*® to dictate answers or compose essays, or writing using a computer). Services must be based on solid research.
5. A *justification* for how much of the student's program *will not* be in general education classroom and school settings.
6. A statement about how the student will *participate in state and district-wide assessments*, particularly those required by the federal accountability procedures, what alternative assessments the student will take (if any), and a justification for these decisions.
7. If the student has significant behavior problems, then the IEP must have a *behavior intervention plan based on a functional assessment* of the student's behavior. (We explore functional assessment in Chapter 7).
8. Beginning at age 14 and by age 16, a statement of needed *transitional services* to move the student toward further education or work in adult life (Friend & Bursuck, 2019; D. C. Smith, Tyler, & Smith, 2014).

To see IEPs for elementary and secondary school students, simply do a Web search for “example IEPs.”

Connect and Extend to PRAXIS II®

Individual Education Programs (IEP) (I, B3)

When you sign an IEP, you are signing an important educational and legal document. Be sure that you can explain the purpose of an IEP, identify its components, and describe the kind of information that can be contained in one.

THE RIGHTS OF STUDENTS AND FAMILIES. Several stipulations in IDEA protect the rights of parents and students. Schools must have procedures for maintaining the confidentiality of student records. Testing practices must not discriminate against students from different cultural backgrounds. Parents have the right to see all records related to the testing, placement, and teaching of their child. If they wish, parents may obtain an independent evaluation of their child. Parents may bring an advocate or representative to the meeting at which the IEP is developed. Students whose parents are unavailable must be assigned a surrogate parent to participate in the planning. Parents must receive written notice (in their native language) before any evaluation or change in placement is made. Finally, parents have the right to challenge the program developed for their child, and they are protected by due process of law. Because teachers often have conferences with these families, the *Guidelines: Family and Community Partnerships* will help make

the meetings more effective; be aware though that these guidelines apply to meetings with all your students and their parents.

Not all students who need special accommodations in school are covered by IDEA or are eligible for the services provided by the law. But these students' educational needs may be covered by other legislation—read on.

Section 504 Protections

As a consequence of the civil rights movement in the 1960s and 1970s, the federal government passed the Vocational Rehabilitation Act of 1973. **Section 504** of that law prevents discrimination against people with disabilities in any program that receives federal money, such as public schools. Through Section 504, all school-age children are ensured an equal opportunity to participate in school activities. The definition of *disability* is broad in Section 504. Two major groups are considered for Section 504 accommodations: students with medical or health needs (e.g., diabetes, drug addiction or alcoholism, severe allergies, communicable diseases, or temporary disabilities resulting from accidents) and students with ADHD, if they are not already covered by IDEA.

If a student has a condition like those listed above that substantially limits participation in school and school-related activities such as field trips, then the school still must develop a plan for giving that student access to education, even though the school gets

Section 504 A part of civil rights law that prevents discrimination against people with disabilities in programs that receive federal funds, such as public schools.

GUIDELINES

FAMILY AND COMMUNITY PARTNERSHIPS

Productive Conferences

Plan and prepare for a productive conference.

Examples

1. Have a clear purpose, and gather the needed information. If you want to discuss student progress, have work samples available.
2. Send home a list of questions, and ask families to bring the information to the conference. Sample questions from Friend and Bursuck (2012, p. 89) are:
 1. What are your priorities for your child's education this year?
 2. What information would you like me to know that would help me better understand and instruct your child? What are your child's learning strengths? Unique needs?
 3. What are the best ways to communicate with you? Phone or voice mail? E-mail or text message? Face to face? Written notes?
 4. What questions do you have about your child's education?
 5. How could we at school help make this the most successful year ever for your child?
 6. Are there any topics you want to discuss at the conference for which I might need to prepare? If so, please let me know.
 7. Would you like other individuals to participate in the conference? If so, please give me a list of their names so I can invite them.
 8. Would you like me to have particular school information available? If so, please let me know.

During the conference, create and maintain an atmosphere of collaboration and respect.

Examples

1. Arrange the room for private conversation. Put a sign on your door to avoid interruptions. Meet around a conference table for better collaboration. Have tissues available.
2. Address families as "Mr." and "Ms." not "Mom" and "Dad" or "Grandma." Use students' names.
3. Listen to families' concerns, and build on their suggestions for their children.
4. Avoid education jargon and acronyms such as *PLAAFP*, *PLOP*, *ADHD*, *IEP*, *FAPE*, *IDEA*.

After the conference, keep good records and follow up on decisions.

Examples

1. Make notes to yourself, and keep them organized.
2. Summarize any actions or decisions in writing, and send a copy to the family and any other teachers or professionals involved.
3. Communicate with families on other occasions, especially when there is good news to share.

For more information about parent conferences, see: scholastic.com/ and search using "parent teacher conference."

TABLE 4.4 • Examples of Accommodations Under Section 504

The types of accommodations that can be written into a Section 504 plan are almost without limit. Some accommodations may relate to physical changes in the learning environment (e.g., air filters are installed to remove allergens). However, many students who have Section 504 plans have functional impairments related to their learning or behavior, and their needs are somewhat similar to those of students with disabilities. A few instructional accommodations that could be incorporated into a Section 504 plan are:

- Seat the student nearest to where the teacher leads most instruction.
- Provide clues such as clock faces indicating beginning and ending times for instruction.
- Establish home–school communication systems for monitoring behavior.
- Fold assignments in half so that the student is less overwhelmed by the quantity of work.
- Make directions telegraphic; that is, concise and clear.
- Record lessons so the student can listen to them again.
- Use multisensory presentation techniques, including peer tutors, experiments, games, and cooperative groups.
- Mark right answers instead of wrong answers.
- Send a set of textbooks to be left at home so that the student does not have to remember to carry books to and from school.
- Provide audio books so the student can listen to assignments instead of reading them.

no extra funds. To get assistance through Section 504, students must be assessed, often by a team, and a plan developed that covers both instruction and extracurricular activities. Unlike IDEA, however, there are fewer rules about how this must happen, so individual schools design their own procedures (Friend & Bursuck, 2019). Look at Table 4.4 to see examples of the kinds of accommodations that might be made for a student. Many of these ideas seem to be “just good teaching.” But I have been surprised to see how many teachers won’t let students use calculators or audio recorders because “they should learn to do it like everyone else!”

The **Americans with Disabilities Act of 1990 (ADA)** prohibits discrimination against persons with disabilities in employment, transportation, public access, local government, and telecommunications. This comprehensive legislation extends the protections of Section 504 beyond the school and workplace to libraries, local and state government, restaurants, hotels, theaters, stores, public transportation, and many other settings.

MyLab Education [Self-Check 4.4](#)

STUDENTS WITH LEARNING CHALLENGES

Before we look at some of the learning challenges children face, let’s overview recent work on the neuroscience of learning difficulties. With all of the new technology, the amount of research on the brain and learning disabilities has grown exponentially.

Neuroscience and Learning Challenges

We now know that many factors also are involved in the learning challenges children face. Certainly injuries, dysfunctions, or diseases of the brain and central nervous system can lead to disabilities in language, mathematics, attention, or behavior. Studies of the brains of students with learning disabilities and with attention-deficit disorders show some differences in structure and activity compared to those of students without problems. For example, students with dyslexia (a language and reading disability) have structural and/or functional differences in the left temporal lobes of their brains (Hallahan, Kauffman, & Pullen, 2015). In people with attention disorders, some areas of the brain

Americans with Disabilities Act of 1990 (ADA) Federal legislation prohibiting discrimination against persons with disabilities in employment, transportation, public access, local government, and telecommunications.

may be smaller. The flow of blood appears to be lower than typical in the cerebellum and frontal lobes, and the levels of some neurotransmitter chemicals and electrical activity are different in certain brain areas, compared to people without attention deficits (Barkley, 2006). Elementary school students with specific language disabilities appear to have immature auditory systems; their brains process basic auditory information in a way similar to the brains of children 3 to 4 years younger (Goswami, 2004). The implications of these brain differences for instruction are still being worked out. It is difficult to determine exactly which came first, the learning problems or the brain differences (Friend, 2014).

Quite a bit of research on learning problems has focused on working memory (discussed in Chapter 8), partly because working memory capacity is a good predictor of a range of cognitive skills including language understanding, reading and mathematics abilities, and fluid intelligence (Bayliss, Jarrold, Baddeley, Gunn, & Leigh, 2005; Tourva et al., 2016). In addition, some studies indicate that children who have learning disabilities in reading and mathematics problem solving have considerable difficulties with working memory (Melby-Lervåg & Hulme, 2013; H. L. Swanson & Jerman, 2006; H. L. Swanson, Zheng, & Jerman, 2009). Specifically, children with learning disabilities have problems using the system of working memory that holds verbal and auditory information while you work with it. Because children with learning disabilities have trouble holding on to words and sounds, it is difficult for them to put the words together to comprehend the meaning of a sentence or to figure out what a math story problem is really asking about.

An even more serious problem may be difficulties retrieving needed information from long-term memory, so it is hard for these children to simultaneously hold on to information (e.g., the result from the first two figures multiplied in an algebra problem) while they have to transform new incoming information, such as the next numbers to add. Important bits of information keep getting lost. Finally, children with learning disabilities in arithmetic and problem solving seem to have problems holding visual-spatial information such as number lines or quantity comparisons in working memory, so creating mental representations of “less than” and “greater than” problems is challenging (D’Amico & Guarnera, 2005).

As you saw in Table 4.3, about 35% of all students receiving some kind of special education services in the public schools are diagnosed as having learning disabilities—by far the largest category of students with disabilities.

Students with Learning Disabilities

How do you explain a student who struggles to read, write, spell, or learn math, even though the student doesn’t have intellectual disabilities, emotional problems, or educational disadvantages and has normal vision, hearing, and language capabilities? The student probably has a **learning disability**, but there is no fully agreed-upon definition of this term. One text on learning disabilities describes 11 definitions (Hallahan et al., 2015), including the definition used in IDEA: “a disorder in one or more of the basic psychological processes involved in understanding or using language, spoken or written, that may manifest itself in imperfect ability to listen, think, speak, read, write, spell, or do mathematical calculation” (p. 117). Most definitions agree that students with learning disabilities perform significantly below what would be expected, given their other abilities. For another widely used definition from the National Joint Committee on Learning Disabilities, go to www.ldonline.org and search “definition.”

Most educational psychologists believe that learning disabilities have both physiological and environmental bases, such as neurological dysfunction, exposure to toxins before birth from mothers who smoked or drank while pregnant, premature birth, poor nutrition, lead-based paint in the home, or lead in the water supply (think of the possible increase in learning disabilities for children in Flint, Michigan, in the coming years). Genetics probably play a role as well. If parents have a learning disability, their children have a 30% to 50% chance of having a learning disability (Friend, 2014; Hallahan et al., 2015).

Learning disability Problem with acquisition and use of language; may show up as difficulty with reading, writing, reasoning, or math.

STUDENT CHARACTERISTICS. Students with learning disabilities are not all alike. The most common characteristics are specific difficulties in one or more academic areas; poor coordination; problems paying attention; hyperactivity and impulsivity; problems organizing and interpreting visual and auditory information; seeming lack of motivation; and difficulties making and keeping friends (Hallahan et al., 2015). As you can see, many students with other disabilities (e.g., ADHD) and many normally developing students may have some of the same characteristics. To complicate the situation even more, not all students with learning disabilities will have these problems, and very few will have all of these characteristics. One student may be 3 years behind in reading but above grade level in math, while another student may have the opposite strengths and weaknesses, and a third may have problems with organizing and studying that affect almost all subject areas.

Most students with learning disabilities have difficulties reading. Table 4.5 lists some of the most common problems, although these problems are not always signs of learning disabilities. For English-speaking students, these difficulties appear to be *phonemic awareness*—problems with relating sounds to letters that make up words, making spelling hard as well (Lyon, Shaywitz, & Shaywitz, 2003; Willcutt et al., 2001). For Chinese speakers, reading disabilities seem to be related to *morphological awareness*, or the ability to combine morphemes into words. Morphemes are the smallest units of meaning that make sense alone. For example, *books* has two morphemes: “book” and “s”—the “s” has meaning because it makes “book” plural. Recognizing units of meaning in Chinese characters is helpful in learning the language (Shu, McBride-Chang, Wu, & Liu, 2006).

Math, both computation and problem solving, is the second most common problem area for students with learning disabilities. Whereas English-speaking students with reading disabilities have trouble associating sounds with letters, students with some math disabilities have difficulty automatically associating numerals (1, 2, 3, etc.) with the correct magnitude—how many is 28, for example. So, before young students learn math computations, some may need extra practice to become automatic in associating numerals with the quantities they represent (Rubinsten & Henik, 2006).

TABLE 4.5 • Reading Problems of Students with Learning Disabilities

Do any of your students show these signs? They could be indications of learning disabilities.

ANXIETY AROUND READING
• Reluctant to read • Cries or acts out to avoid reading • Seems tense when reading
DIFFICULTY RECOGNIZING WORDS OR LETTERS
• Inserts an incorrect word, substitutes or skips words • Reverses letters or numbers—48 for 84, for example • Mispronounces words—“cape” for “cope” • Mixes up order of words in sentences: “I can bikes ride” for “I can ride bikes.” • Reads very slowly and with little fluency—starts and stops often
POOR VOCABULARY SKILLS
• Can’t read new vocabulary words • Has limited vocabulary
DIFFICULTY WITH UNDERSTANDING OR REMEMBERING WHAT WAS READ
• Can’t recall basic facts from the reading • Can’t make inferences or identify the main idea

The writing of some students with learning disabilities is virtually unreadable, and their spoken language can be halting and disorganized, as you can see in Figure 4.4. Students with learning disabilities often lack effective ways of approaching academic tasks. They don't know how to focus on the relevant information, get organized, apply learning strategies and study skills, change strategies when the one being used isn't working, or evaluate their learning. They tend to be passive learners, in part because they don't know how to learn—they have failed so often. Working independently is especially trying, so they often leave homework and seatwork incomplete (Hallahan et al., 2015).

TEACHING STUDENTS WITH LEARNING DISABILITIES. Early diagnosis is important so that students with learning disabilities do not become terribly frustrated and discouraged. The students themselves do not understand why they are having such trouble, and they may become victims of **learned helplessness**. This condition was first identified

FIGURE 4.4

If I could I'd be a
eagry, I would...

~~go~~ go home and
do my work. I'd be on
my faster truck and
rebel'd the motor. fix
my motor on my rider.
or watch my TV in my
room. play with my friends.
she is a lot of fun
to play with she will
bite your feet or get
in your stuff... I can
go out and run the
bouncing bag. climb a tree.
run around the block
copy all times. it is fun
for me to do that.
I would play with
a dog that is half
my size and rubbing with
him.

Learned helplessness The expectation, based on previous experiences with a lack of control, that all of one's efforts will lead to failure.

Source: Friend, M. & Bursuck, W. D. (2019) *Including Students with Special Needs: A Practical Guide for Classroom Teachers* (8th Ed.). Reprinted by permission of Pearson Education, Inc.

in learning experiments with animals. The animals were put in situations in which they received punishment (electric shocks) that they could not control. Later, when the situation was changed and they could have escaped the shocks or turned them off, the animals didn't even bother trying (Seligman, 1975). They had learned to be helpless victims. Students with learning disabilities may also come to believe that they cannot control or improve their own learning. This is a powerful misconception. These students never exert the effort to discover that they can make a difference in their own learning, so they remain passive and helpless.

Students with learning disabilities may also try to compensate for their problems and develop bad learning habits in the process, or they may begin avoiding certain subjects out of fear of not being able to handle the work. To prevent these things from happening, teachers should refer the students to the appropriate professionals in the school as early as possible.

Three general approaches, preferably used together, are highly effective for students with learning disabilities (Friend, 2014; Hallahan et al., 2015). The first is *direct instruction*, described in Chapter 14. The basics of this approach are clear explanations and demonstrations of new material, teaching in small steps with practice after each step, immediate feedback, and teacher guidance and support. The second general approach is *peer tutoring*. This can be done at the classroom level when teachers train and monitor students who act as peer tutors. We will explore this possibility in Chapter 10. The third approach is *strategy instruction*, described in Chapter 9. Strategies are specific rules for focusing attention and accomplishing tasks, such as *TREE* for supporting elementary students' persuasive writing.

Topic sentence: Tell what you believe.

Reasons: Tell three or more reasons why you believe this. Will your readers believe this?

Ending: Wrap it up!

Examine: Check for all three parts.

All strategies have to be taught using good direct instruction—explanation, examples, and practice with feedback. See Chapters 9 and 14 for more details.

Here are some other general strategies for working with students with learning disabilities. In the preschool and elementary years, keep verbal instructions short and simple; have students repeat directions back to you to be sure they understand; give multiple examples and repeat main points several times; allow more practice than usual, especially when the material is new. Many of these strategies are useful in secondary grades as well. In addition, directly teach older students self-monitoring strategies, such as cueing students to ask, “Was I paying attention?” Teach students to use external memory strategies such as note taking and devices such as assignment books, to-do lists, or electronic calendars (Hardman et al., 2015). In every grade, connect new material to knowledge students already have. You may be thinking that these are good ideas for many students who need more support and direct teaching of study skills. You are right.

Students with Hyperactivity and Attention Disorders

PUT YOURSELF IN THEIR PLACE If a student is struggling with time management and organization issues, what kind of accommodations would you provide? •

You probably have heard of and may even have used the term *hyperactivity*. The notion is a modern one; there were no “hyperactive children” 50 to 60 years ago. Such children, like Mark Twain's Huckleberry Finn, were seen as rebellious, lazy, or “fidgety” (Nylund, 2000). Today, ADHD is common. About 11% of children in the United States have been diagnosed with ADHD at some point in their lives, and from 5% to 7% of children around the world also are affected (DuPaul & Jimerson, 2014). Closer to home, many student teachers in my program have classes that include 5 or 6 students diagnosed as

Connect and Extend to PRAXIS II

ADHD (I, B2)

A new student's parent calls you to tell you that a neurologist has diagnosed her child with ADHD. What typical behaviors can you expect from the student? What can you do to support that student's development?

MyLab Education Video Example 4.3

In this video, two student teachers discuss their observations and experiences with students who have ADHD. They make suggestions about teaching strategies that work and strategies that are ineffective with these students.

Attention-deficit hyperactivity disorder (ADHD) Current term for disruptive behavior disorders marked by overactivity, excessive difficulty sustaining attention, or impulsiveness.

“hyperactive,” and in one class, 10 students had that diagnosis. Even closer, several of my immediate family members have ADHD.

DEFINITIONS. Hyperactivity is not one particular condition, but two kinds of problems that may or may not occur together: *attention disorders* and *impulsive-hyperactivity* problems. About half the children diagnosed in the United States have both conditions. The American Psychiatric Association defines **attention-deficit hyperactivity disorder (ADHD)** as a neurodevelopmental disorder affecting both children and adults. It is a persistent or ongoing pattern of inattention and/or hyperactivity-impulsivity that gets in the way of an individual's daily life or typical development (American Psychiatric Association, DSM-5, 2013b). Some indicators are:

- **Inattention:** Doesn't pay close attention to class activities, details of work, teacher directions, or class discussions; can't organize work, notebooks, desk, or assignments; easily distracted and forgetful; loses things; procrastinates on long assignments; doesn't study effectively for exams; cheats on tests or assignments.
- **Hyperactivity/impulsivity:** Fidgets and squirms; can't stay in assigned seat; can't move slowly—seems driven by a motor to go fast; talks excessively; blurts out answers; has trouble waiting for a turn; interrupts; rushes through assignments; cuts in line.

Today, most psychologists agree that the main problem for children labeled hyperactive is directing and maintaining attention, not simply controlling their physical activity. Students with ADHD also have trouble with task switching—once they get started on an activity, it is difficult for them to stop and start a new one (Hallahan et al., 2015). All children show some of these behaviors some of the time, but children with ADHD are likely to have some of these symptoms before age 7, the symptoms occur across many settings (not just school), and the symptoms lead to problems with learning and getting along with others. Students with ADHD, particularly adolescents, have trouble planning, managing time, and completing schoolwork. They are more likely to fail in school, repeat a grade, be suspended or expelled from school, change schools, be referred to special education, and experience anxiety and depression (Martin, 2014; Sibley, Altszuler, Morrow, & Merrill, 2014).

ADHD usually is diagnosed in elementary school, but research suggests that problems with attention and hyperactivity may begin to show up as early as 3 years of age (Friedman-Weieneth, Harvey, Youngsirth, & Goldstein, 2007). Even though about 2 to 5 times more boys than girls are identified as hyperactive, the gap appears to be narrowing. Girls have the same symptoms as boys but tend to show the symptoms in less obvious ways, so they may not be identified as often and thus may miss getting appropriate support (Friend, 2014).

Just a few years ago, most psychologists thought that ADHD diminished as children entered adolescence, but now evidence shows that the problems can persist into adulthood for at least half of those diagnosed with ADHD (Hirvikoski et al., 2011). Adolescence—with the increased stresses of puberty, transition to middle or high school, more demanding academic work, and more engrossing social relationships—can be an especially difficult time for students with ADHD (E. Taylor, 1998). When children diagnosed with ADHD become adults, about 25% experience no more symptoms, 50% have enough symptoms to be diagnosed with ADHD, and about 25% have residual symptoms that can still interfere with their lives, so ADHD definitely is a problem for adults, too (Hallahan et al., 2015; Rosenberg et al., 2011). In fact, some recent research points to the possibility that ADHD may develop in adulthood, even without symptoms in childhood (Reddy, 2016).

TREATING ADHD WITH DRUGS. Today, drug therapy for ADHD is increasing, but this approach is controversial, as you can see in the *Point/Counterpoint*.

ALTERNATIVES/ADDITIONS TO DRUG TREATMENTS. Gregory A. Fabiano and his colleagues (2009) identified 174 studies conducted between 1967 and 2006 that included almost 3,000 participants in behavioral treatments for ADHD; all studies met rigorous standards of quality research. Behavioral treatments involve the application of methods

POINT/COUNTERPOINT: Pills or Skills for Children with ADHD?

About 3% of school-age children in the United States (ages 6 to 18) take some kind of medication for ADHD. Should children with ADHD be given drugs?

POINT ▶ **Yes, drugs are helpful in ADHD.** About 30% of the people who take Ritalin, the most commonly prescribed ADHD drug, respond well (Hallahan et al., 2015). Ritalin and other prescribed drugs such as Adderall, Focalin, Dexadrine, Vyvanse, and Cylert are stimulants. In particular dosages that vary by individual, they appear to influence the release of neurotransmitters and help the executive functions of the brain to operate more normally (Hallahan et al., 2015). Short-term effects include possible improvements in behaviors, including increased cooperation, attention, task switching, and compliance. Research suggests that about 70% to 80% of children with ADHD are more manageable and better able to benefit from educational and social interventions when on medication (Hutchinson, 2009). In fact, both stimulants such as Adderall and Ritalin and nonstimulant treatments such as Strattera appear to have some helpful effects for many children and adolescents with ADHD (Kratchovil, 2009). Positive results also have been reported with Buspar, typically used to treat anxiety, and even with some supplements such as pycnogenol (Trebaticka et al., 2009). And some evidence indicates that Strattera might have positive effects on working memory, planning, and inhibition—at least for the Chinese children studied (Yang et al., 2009).

COUNTERPOINT ▶ **No, drugs should not be the first treatment tried with ADHD.** Many children have negative side effects from drugs such as increased heart rate and higher blood pressure, interference with growth rate, insomnia, weight loss, and nausea (D. C. Smith et al., 2014). For most children, these side effects are mild and can be controlled by adjusting the dosage and timing of the drug. However, little is known about the long-term effects of drug therapy. The drug Strattera is not a stimulant, but use may lead to increased thoughts of suicide. As a parent or teacher, you need to keep up with the research on treatments for ADHD.

Many studies have concluded that the improvements in behavior resulting from use of the drugs *seldom* lead to improvements in academic learning or peer relationships, two areas where children with ADHD have great problems. Because children appear to improve dramatically in their behavior, parents and teachers, relieved to see change, may assume the problem has been cured. It hasn't. The children still need special help in learning, especially interventions focused on task switching and how to make *connections* among elements in readings or presentations in order to build coherent, accurate representations of the information (Bailey et al., 2009; Doggett, 2004; Purdie, Hattie, & Carroll, 2002).

Beware of Either/Or. The bottom line is that even if students in your class are on medication, it is critical that they also learn the academic and social skills they will need to succeed—*this will not happen by itself*. Students need to learn how and when to apply learning strategies and study skills. Also, they need to be encouraged to persist when challenged by difficult tasks and to see themselves as having control over their learning and behavior. Medication alone will not make this happen, but it may help. We need to attack the problem on several fronts with effective teaching, counseling, and supports for positive behaviors.

derived from behavioral learning theories such as contingency management, time-out, shaping, self-regulation, and modeling (see Chapters 7 and 11). The researchers then compared treated with untreated groups or individuals before and after one or more different kinds of treatments. Their conclusion? Findings were clear and impressive. “Based on these results, there is strong and consistent evidence that behavioral treatments are effective for treating ADHD” (Fabiano et al., 2009, p. 129). Because these approaches seem to work, we as teachers need to learn when and how to use them (Hirvikoski et al., 2011). Researchers working with adults in Sweden also found that behavioral methods stressing a balance between accepting and changing ADHD symptoms and behaviors proved effective.

Lessons for Teachers: Learning Disabilities and ADHD

Long assignments may overwhelm students with learning disabilities and attention deficits, so give them a few problems or paragraphs at a time with clear consequences for completion. If the student is highly distractible, consider creating a learning cubicle that

blocks outside sights and sounds. Post a classroom schedule and give clear signals when transitions are coming. Help students organize their desks, materials, notebooks, backpacks, assignment sheets, or electronic calendars. Another promising approach combines instruction in learning and memory strategies with motivational training. The goal is to help students develop the “skill and will” to improve their achievement. They are also taught to monitor their own behavior and encouraged to be persistent and to see themselves as “in control” (Pfiffner, Barkley, & DuPaul, 2006).

The notion of being in control is part of a therapy strategy for dealing with ADHD that stresses personal agency. Rather than treating the problem child, David Nylund’s (2000) approach enlists the child’s strengths to conquer his or her problems—to put the child in control. New metaphors for the situation are developed. Rather than seeing the problems as inside the child, Nylund helps everyone see ADHD, Trouble, Boredom, and other enemies of learning as outside the child—demons to be conquered or unruly spirits to be enlisted in the service of what the child wants to accomplish. The focus is on solutions.

As a teacher, you can look for times when the student is engaged—even short times. What is different about these times? Discover the student’s strengths, and allow yourself to be amazed by them. Make changes in your teaching that support the changes the student is trying to make. Students with ADHD have some suggestions, too, as you can see in Table 4.6 taken from Nylund (2000, pp. 202–203).

Students with Communication Disorders

Students with communication disorders who are between the ages of 6 and 21 are the second largest group served by special education. These students may have language disorders, speech disorders, or both. They make up about 20% of students receiving services. Communication disorders can arise from many sources, because so many different aspects of the individual are involved in learning language and using speech. A child with a hearing impairment will not learn to speak normally. Injuries can cause neurological problems that interfere with speech or language. Children who are not listened to, or whose perception of the world is distorted by emotional problems, will reflect these problems in their language development. Because speaking involves movements, any impairment of the motor functions involved with speech can cause language disorders. And because language development and thinking are so interwoven, any problems in cognitive functioning can affect ability to use language.

SPEECH DISORDERS. Students who cannot produce sounds effectively for speaking are considered to have a **speech disorder**. About 5% of school-age children have some form of speech impairment. Articulation problems and **fluency disorders** (stuttering) are the two most common problems.

Articulation disorders include distorting a sound like a lisp (*thumtimes* for *sometimes*), substituting one sound for another (*shairp* for *chair*), adding a sound (*chuch air*

Speech disorder Inability to produce sounds effectively for speaking.

Fluency disorder A language disorder characterized by disruptions in the production of speech sounds, commonly called stuttering.

Articulation disorders Any of a variety of pronunciation difficulties, such as the substitution, distortion, or omission of sounds.

TABLE 4.6 • Students with ADHD Give Teachers Advice

Students with ADHD made these recommendations for their teachers (Nylund, 2000):

- Use lots of pictures (visual clues) to help me learn.
- Recognize cultural and racial identity.
- Know when to bend the rules.
- Notice when I am doing well.
- Don’t tell the other kids that I am taking Ritalin.
- Offer us choices.
- Don’t just lecture—it’s boring!
- Realize that I am intelligent.
- Let me walk around the classroom.
- Don’t give tons of homework.
- More recess!
- Be patient.

for *chair*), or omitting sounds (*chai* for *chair*) (Rosenberg et al., 2011). Keep in mind, however, that most children are 6 to 8 years old before they can successfully pronounce all English sounds in normal conversation. The sounds of the consonants *l*, *r*, *y*, *s*, *v*, and *z* and the consonant blends *sh*, *ch*, *ng*, *zh*, and *th* are the last to be mastered (Friend, 2014). Also, there are dialect differences based on geography that do not represent articulation problems. A child in your class who is from New England might say “ideer” for “idea,” but have no speech impairment.

Stuttering (fluency disorder) generally appears between the ages of 3 and 4. Causes of stuttering are unknown but might include emotional or neurological problems or learned behavior. If stuttering continues more than a year or so, the child should be referred to a speech therapist. Early intervention can make a big difference (Hallahan et al., 2015; Hardman et al., 2014). When you are working with a student who stutters, speak to the child often, privately, and without hurrying, interrupting, or finishing the child’s words and sentences. Pause often, especially after the child finishes speaking. Communicate that it is OK to take time to think before you speak. Notice when the stuttering is more and less frequent. Avoid pressuring the child to speak quickly. In class discussions, call on the child early in the discussion so tension won’t build up, and ask a question that can be answered with few words. Speak frankly about the stuttering, but assure the student it is nothing to be ashamed of—many successful people, including kings, have shared the challenge and learned to improve (Friend, 2014; Rosenberg et al., 2011).

Voicing problems, a third type of speech impairment, include speaking with an inappropriate pitch, quality, or loudness, or in a monotone. A student with any of these problems should be referred to a speech therapist. Recognizing the problem is the first step. Be alert for students whose pronunciation, loudness, voice quality, speech fluency, expressive range, or rate is very different from that of their peers. Pay attention also to students who seldom speak. Are they simply shy, or do they have difficulties with language?

LANGUAGE DISORDERS. Language differences are not necessarily language disorders. Students with language disorders are markedly deficient in their ability to understand or express language, compared with other students of their own age and cultural group (Owens, 2012). Students who seldom speak, who use few words or very short sentences, or who rely only on gestures to communicate should be referred to a qualified school professional for observation or testing. Table 4.7 gives ideas for promoting language development for all students.

TABLE 4.7 • Encouraging Language Development

- Talk about things that interest children.
- Follow the children’s lead. Reply to their initiations and comments. Share their excitement.
- Don’t ask too many questions. If you must, use questions such as *how did/do*, . . . *why did/do*, . . . and *what happened* . . . that result in longer explanatory answers.
- Encourage children to ask questions. Respond openly and honestly. If you don’t want to answer a question, say so, and explain why. (*I don’t think I want to answer that question; it’s very personal*)
- Use a pleasant tone of voice. You need not be a comedian, but you can be light and humorous. Children love it when adults are a little silly.
- Don’t be judgmental or make fun of children’s language. If you are overly critical of children’s language or try to catch and correct all errors, they will stop talking to you.
- Allow enough time for children to respond.
- Treat children with courtesy by not interrupting when they are talking.
- Include children in family and classroom discussions. Encourage participation and listen to their ideas.
- Be accepting of children and of their language. Hugs and acceptance can go a long way.
- Provide opportunities for children to use language and to have that language work for them to accomplish their goals.

Voicing problems
Inappropriate pitch, quality, loudness, or intonation.

Students with Emotional or Behavioral Difficulties

Students with **emotional and behavioral disorders** can be among the most difficult to teach in a general education class, and they are a source of concern for many prospective teachers (Avramidis, Bayliss, & Burden, 2000). The future is not bright for students with emotional and behavioral disorders who do not get appropriate help. About one-third of these students are arrested during their school years. After high school, they are less likely to keep a job and more likely to be arrested than their peers who do not have disabilities (Harrison, Bunford, Evans, & Owens, 2013), so early intervention is really important.

Professionals in education define behavioral disorders as behaviors that deviate so much from the norm that they interfere with the child's own growth and development and/or the lives of others. The language in IDEA describes emotional disturbances that involve inappropriate behaviors, unhappiness or depression, fears and anxieties, and trouble with relationships. Table 4.8 shows the IDEA definition.

However they are defined, what you will observe as a teacher are students who are aggressive, anxious, withdrawn, or depressed and who often have difficulty following rules, paying attention, staying in their seats, or interacting with others. They often get sent to the principal's office or excluded from class. Almost 350,000 students in the United States have emotional disturbances, making this the fifth-largest group receiving services. This number has increased about 20% since 1991–1992. As with learning disabilities and ADHD, more boys than girls are diagnosed with these disorders—at least three times as many boys as girls are identified. One troubling fact is that African American students are overrepresented in this category. They make up about 13% of the total population but about 26% of the students identified with emotional and behavioral disorders.

The range of possible emotional and behavioral disorders is wide. And students with other disabilities—learning disabilities, intellectual disabilities, or ADHD, for example—may also have emotional or behavioral problems as they struggle in school. Methods from applied behavior analysis (Chapter 7) and direct teaching of self-regulation skills (Chapter 11) are two useful approaches. Another possibility that has proved helpful for these students is to provide structure, organizational tools, and choices. Here are some ideas from Terri Swanson (2005):

- Structure the environment by minimizing visual and auditory stimulation, establishing clear visual boundaries between areas where different behaviors are expected, or organizing supplies in easy-to-use holders.
- Structure schedules by posting monthly and daily schedules, having clear starting and ending signals and clear procedures for turning in work.
- Structure activities by color-coding subject folders (blue for math, etc.), posting verbal instructions with visual prompts, or putting all materials needed for an activity in a “Science box.”
- Structure rules and routines, for example, giving students a script to use in asking other students to play a game with them, writing rules in a positive way, or preparing

TABLE 4.8 • IDEA Definition of Emotional Disturbance

Emotional disturbance means a condition exhibiting one or more of the following characteristics over a long period of time and to a marked degree that adversely affects a child's educational performance:

- An inability to learn that cannot be explained by intellectual, sensory, or health factors.
- An inability to build or maintain satisfactory interpersonal relationships with peers and teachers.
- Inappropriate types of behavior or feelings under normal circumstances.
- A general pervasive mood of unhappiness or depression.
- A tendency to develop physical symptoms or fears associated with personal or school problems.
- Emotional disturbance includes schizophrenia. The term does not apply to children who are socially maladjusted, unless it is determined that they have an emotional disturbance.

MyLab Education Video Example 4.4

The general education teacher and special education teacher shown here work together effectively to provide structure, organizational tools, and support for students with emotional and behavioral disorders.

Emotional and behavioral disorders Behaviors or emotions that deviate so much from the norm that they interfere with the child's own growth and development and/or the lives of others—inappropriate behaviors, unhappiness or depression, fears and anxieties, and trouble with relationships.

students for changes in routines such as spring break by reviewing pictures of what will be happening over the break.

- Offer choices by providing a short list of alternatives for completing assignments or projects.

Because students with emotional and behavioral disorders frequently break rules and push the limits, teachers often find themselves disciplining them. Be aware that there have been court rulings on disciplining students with serious emotional problems (Yell, 1990). The *Guidelines: Disciplining Students with Emotional Problems* may help when you are faced with these situations.

Let's consider an area where teachers may be able to detect problems and make a difference—suicide.

SUICIDE. Of course, not every student with emotional or behavioral problems will consider suicide, but depression often is associated with suicide. Up to 10% of adolescents have attempted suicide at some point, but even more have considered it. Native Americans and students living in rural communities are more likely to commit suicide. There are several general risk factors, and they seem to apply to both male and female African American, Latino, and White adolescents: depression and substance abuse, history of

GUIDELINES

Disciplining Students with Emotional Problems

Be careful not to violate the due process rights of students. Students and parents must know the behaviors expected and the consequences for misbehavior.

Examples

1. Communicate expectations clearly and in writing.
2. Ask parents and students to sign a copy of the classroom rules.
3. Post rules and consequences in class and on a class Web page.

Be very careful with severe punishments that remove students from class for a long time. These constitute a change in the child's IEP and require due process.

Examples

1. Always follow due process for suspensions of more than 10 days.
2. Be aware of possible due process requirements for prolonged periods of time-out (in-school suspension).

Ensure that punishments for students with severe emotional problems serve a clear educational purpose.

Examples

1. Give a rationale for punishment or correction that ties an action to a student's learning or the learning of others in the class.
2. Use written behavior contracts that include a rationale.

Make sure the rule and the punishment are reasonable.

Examples

1. Consider the student's age and physical condition.

2. Does the punishment match the offense and the way others in the class are treated?
3. Do other teachers handle similar situations in the same way?
4. Try less intrusive punishments first. Be patient. Move to more severe actions only when less severe procedures fail.

Keep good records, and work collaboratively so all involved are informed.

Examples

1. Document the punishment of all students in a journal or log. List what precipitated the punishment, what procedures were used, how long the punishment lasted, the results, modifications to the punishment, and new results.
2. Note meetings with families, special education teachers, and the principal.
3. Make any changes involving management plans with families and other teachers.

Always use positive consequences in conjunction with negative ones.

Examples

1. If students lose points for breaking rules, give them ways to regain points through positive behavior.
2. Recognize genuine accomplishments and small steps—DON'T say, "Well, it's about time you. . . ."

For more information on disciplining students with disabilities, go to www.wrightslaw.com and search "disciplining students with disabilities."

suicide in the family, being under stress, tendency to be impulsive or perfectionistic, belief that a person goes to a better place after dying, and family rejection or conflict. Having more than one of these risk factors is especially dangerous (Arnett, 2013; Friend, 2014; Steinberg, 2005). In addition, some drugs prescribed for depression or ADHD may increase the risk of suicide in adolescents.

Suicide often comes as a response to life problems—problems that parents and teachers sometimes dismiss. There are many warning signs that trouble is brewing. Watch for changes in eating or sleeping habits, weight, grades, disposition, activity level, and drug or alcohol use, or a declining interest in friends or activities that were once fun. Students at risk sometimes suddenly give away prized possessions such as iPads, games, clothing, or pets. They may seem depressed or hyperactive and may say things like, “Nothing matters anymore,” “I shouldn’t be here,” “If I died, people might love me more,” “You won’t have to worry about me anymore,” or “I wonder what dying is like.” They may start missing school or quit doing work. It is especially dangerous if the student not only talks about suicide but also has a plan for carrying it out. And sometimes the suicide risk increases as depression decreases because deeply depressed young people are immobilized and don’t have the energy to plan or make a suicide attempt. If a student who has been depressed suddenly seems much better, it could be that he or she has firmly decided to end the pain with suicide, so be alert and in communication with that student (Arnett, 2013). Table 4.9 provides some myths and facts about suicide.

If you suspect that there is a problem, talk to the student directly, and ask about his or her concerns. One feeling shared by many people who attempt suicide is that no one cared enough to ask. Ask about specifics, and take the student seriously. You may need to become an advocate for the student with administrators, parents, or other adults who dismiss the warning signs. Also, be aware that teenage suicides often occur in clusters. After one student acts or when stories about a suicide are reported in the media, other teens are more likely to copy the suicide (Lewinsohn, Rohde, & Seeley, 1994; F. P. Rice & Dolgin, 2002).

TABLE 4.9 • **Myths and Facts about Suicide**

Myth	People who talk about suicide don’t kill themselves, they are just trying to get attention.
Fact	People who die by suicide usually talk about it first. They are in pain and often reach out for help because they do not know what to do and have lost hope. Always take talk about suicide seriously. Always.
Myth	Only certain types of people commit suicide.
Fact	All types of people commit suicide—male and female, young and old, rich and poor, country people and city people. It happens in every racial, ethnic, and religious group.
Myth	You should never ask people who are suicidal if they are thinking about suicide or if they have thought about a method, because just talking about it will give them the idea.
Fact	Asking people if they are thinking about suicide does not give them the idea for suicide. And it is important to talk about suicide with people who are suicidal because you will learn more about their mindset and intentions, and allow them to diffuse some of the tension that is causing their suicidal feelings.
Myth	Most people who kill themselves really want to die.
Fact	The vast majority of people who are suicidal do not want to die. They are in pain, and they want to stop the pain. Suicide is often intended as a cry for help.
Myth	Young people never think about suicide, they have their entire life ahead of them.
Fact	Suicide is the third leading cause of death for young people ages 15 to 24. Even children under 10 have committed suicide.

DRUG ABUSE. Modern society makes growing up a very confusing process. Notice the messages from films and billboards. “Beautiful,” popular, happy people drink alcohol and smoke cigarettes, with little concern for their health. Males are encouraged to “drink like a man!” We have over-the-counter drugs for almost every common ailment, and constant ads from drug companies broadcast the benefits of new prescription medications. Coffee or an “energy drink” wakes us up, and a pill helps us sleep. And then we tell students to “say no!” to drugs.

For many reasons, not just because of these contradictory messages, drug use has become a significant problem for students. Accurate statistics are hard to find, but estimates from the *Monitoring the Future* survey by researchers at the University of Michigan (Johnston, Miech, O’Malley, Bachman, & Schulenberg, 2016) indicate that 6.9% of eighth graders, 15.9% of tenth graders, and 24.4% of twelfth graders reported using an illicit drug, including inhalants and marijuana, *in the past 30 days*, with marijuana being the most popular for younger students and alcohol for twelfth graders (see Table 4.10 for more information from the *Monitoring the Future* study). In fact, marijuana use increased among older teens from 2008 through 2016—the last data available when I wrote this chapter, with about 1% of eighth graders, 3% of tenth graders, and 6% of twelfth graders reporting they use marijuana *daily*. Younger adolescents are more likely to use inhalants (glues, paint thinners, nail polish remover, aerosol sprays, etc.). These are inexpensive and available. And students don’t realize that they are risking injury or death when they use inhalants. Abusing drugs is especially dangerous for African American males. In one study that followed a sample of adolescents from age 19 to 27, about 33% of the African American young men who abused drugs died by age 27, compared to 3% for White males. The death rate for both African American and White females who abused drugs was 1% (D. B. Clark, Martin, & Cornelius, 2008).

Even though drug use remains a problem for some students, it is hopeful that the use of all drugs except marijuana for twelfth graders has declined significantly since the 1990s (Johnson et al., 2016).

PREVENTION. We should distinguish between experimentation and abuse. Many students try something at a party but do not become regular users. Providing information or “scare” tactics such as the DARE drug prevention program seems to have little positive

TABLE 4.10 • **Percentage of Students in the United States Grades 8 through 12 Who Reported Using these Drugs in the Past 30 Days**

DRUG	EIGHTH GRADE	TENTH GRADE	TWELFTH GRADE
Any illicit drug	6.9	15.9	24.2
Marijuana	5.4	14.0	22.5
Inhalants	1.8	1.0	.8
Ecstasy	.3	.5	.9
Cocaine	.3	.4	.9
Heroin	0.2	.2	.2
Amphetamines	1.7	2.7	3.0
Been drunk	1.8	9.0	20.4
Cigarettes	2.6	6.3	10.5
Smokeless tobacco	2.5	3.5	6.6
E-cigarette	6.2	11.0	12.5

effect and may even encourage curiosity and experimentation (Dusenbury & Falco, 1995; Tobler & Stratton, 1997).

So what is more effective? Adam Fletcher and his colleagues analyzed research on school programs around the world. One overwhelmingly frequent finding was that after taking into account students' prior drug use and personal characteristics, "disengagement from school and poor teacher–student relations were associated with subsequent drug use and other risky health behaviors" (Fletcher, Bonell, & Hargreaves, 2008, p. 217). For example, the researchers describe one study that found that being disconnected from school predicted young adolescents' drug use 2 to 4 years later. Thus engaging adolescents in schools, forming positive relationships, and connecting the students to caring adults and peers are all critical in preventing drug abuse.

Students with Intellectual Disabilities

A word about terms. **Intellectual disability** is a more current name for **mental retardation**. You may also have heard the terms *cognitive impairment*, *general learning disability*, *developmental disability*, or *cognitive disability*. Intellectual disability is the preferred name, because the term *mental retardation* is considered offensive and stigmatizing; however, mental retardation still is used in the IDEA definitions and in many schools. In 2007, the American Association on Mental Retardation changed its name to the American Association on Intellectual and Developmental Disabilities (AAIDD) to reflect this rejection of the term *mental retardation*. The AAIDD definition of *intellectual disability* is "a disability characterized by significant limitations in both intellectual functioning and adaptive behavior as expressed in conceptual, social, and practical adaptive skills. This disability originates before age 18" (AAIDD.org).

Intellectual function is usually measured by IQ tests, with a score below 70 being one of the indicators. But an IQ score below 70 is not enough to diagnose a child as having intellectual disabilities. There must also be problems with adaptive behavior, day-to-day independent living, and social functioning. This caution is especially important when interpreting the scores of students from different cultures. Defining disability based on test scores alone can result in students who are perceived as disabled at school, but viewed as having no disabilities at home or in their community.

Less than 1% of the population fits the AAIDD's definition of disability in both intellectual functioning and adaptive behavior. This group is further divided by the AAIDD based on the amount of support that a person requires to function at his or her highest level. Support varies from intermittent (e.g., as needed during stressful times), to limited (consistent support, but time-limited, such as employment training), to extensive (daily care, such as living in a group home), to pervasive (constant, high-intensity care for all aspects of living) (Hallahan et al., 2015).

As a general education teacher, you may not have contact with children needing *extensive* or *pervasive* support unless your school is participating in a full-inclusion program, but you probably will work with children needing *intermittent* or *limited* support. In the early grades, these students may simply learn more slowly than their peers. They need more time and more practice to learn, and they may have difficulty transferring learning from one setting to another or putting small skills together to accomplish a more complex task. They often have difficulties with skills required to plan, monitor, and redirect attention and learning strategies (T. Simon, 2010), so very structured and complete teaching and guidance make sense. The *Guidelines: Teaching Students with Intellectual Disabilities* list more suggestions.

Learning goals for students with intellectual disabilities depend on the amount of support needed—the less support needed and the less severe the disability, the more you can focus on academic skills. The greater the degree of disability, the more teaching should stress learning about the local environment; social behavior; personal interests; vocational and domestic skills; literacy for living (reading signs, labels, and newspaper ads; completing a job application); job-related behaviors such as courtesy and punctuality; health self-care; and citizenship skills. Teach what the student is ready to learn, but always include academic skills at appropriate levels along with life skills

Intellectual disabilities/ Mental retardation

Significantly below-average intellectual and adaptive social behavior, evident before age 18.

GUIDELINES

Teaching Students with Intellectual Disabilities

1. Develop specific learning objectives based on an analysis of each student's learning strengths and weaknesses. No matter what a student knows, he or she is ready to learn the next step.
2. Work on practical skills and concepts based on the demands of adult life.
3. Analyze the task the student will be learning: Identify the specific steps involved in successful completion, and don't overlook any steps in your planning.
4. State and present objectives simply.
5. Present material in small, logical steps. Practice extensively before going on to the next step. Use resources such as computer drill-and-practice exercises in class, or have volunteers and family members continue guiding practice outside class.
6. Do not skip steps. Students with average intelligence can form conceptual bridges from one step to the next and make metacognitive judgments about how they are doing, but children with below-average intelligence need every step and bridge made explicit. Make connections for the student. Do not expect him or her to "see" the connections.
7. Be prepared to present the same idea in many different ways using different representations (verbal, visual, hands on, etc.).
8. Go back to a simpler level if you see the student is not following.
9. Be especially careful to motivate the student and maintain attention. Allow and encourage different ways of expressing understanding—written, drawings, oral responses, gestures, and so on.
10. Find materials that do not insult the student. A middle school boy may need the low vocabulary of "See Spot run," but will be insulted by the age of the characters and the content of the story.
11. Focus on a few target behaviors or skills so you and the student have a chance to experience success. Everyone needs positive reinforcement.
12. Be aware that students with below-average intelligence must overlearn, repeat, and practice more than children of average intelligence. They must be taught how to study, and they must frequently review and practice their newly acquired skills in different settings.
13. Pay close attention to social relations. Simply including students with below-average intelligence in a general education class will not guarantee that they will be accepted or that they will make and keep friends.
14. Establish peer tutoring programs, and train all students in the class to serve as tutors and as tutees—see Chapter 10 for specifics.

For more information, see aaidd.org/

(Hallahan et al., 2015). Today, there is a growing emphasis on **transition programming**—preparing the student to live and work in the community. As you saw earlier in the chapter, the law requires that schools design an IEP for every child with disabilities. An ITP (individualized transition plan) may be part of the IEP for students with intellectual disabilities (Friend, 2014).

Students with Health and Sensory Impairments

Some health impairments you may encounter are cerebral palsy, seizure disorders, asthma, sickle cell disease, diabetes, visual impairments, and hearing impairments.

CEREBRAL PALSY AND MULTIPLE DISABILITIES. Damage to the brain before or during birth or during infancy can cause a child to have difficulty coordinating his or her body movements. The problem may be very mild, so the child simply appears a bit clumsy, or so severe that voluntary movement is practically impossible. The most common form of **cerebral palsy** is characterized by **spasticity** (overly tight or tense muscles). Many children with cerebral palsy also have secondary handicaps. In the classroom, these secondary handicaps are the greatest concern—and these are usually what the general education teacher can help with most. For example, many children with cerebral palsy also have visual impairments or speech problems, and about 50% to 60% have mild-to-severe intellectual disabilities. But many students with cerebral palsy are average to well above average in measured intelligence (Pellegrino, 2002).

Transition programming Gradual preparation of students with special needs to move from high school into further education or training, employment, or community involvement.

Cerebral palsy Condition involving a range of motor or coordination difficulties due to brain damage.

Spasticity Overly tight or tense muscles, characteristic of some forms of cerebral palsy.

SEIZURE DISORDERS (EPILEPSY). A seizure is a cluster of behaviors that occurs in response to abnormal neurochemical activities in the brain (Hardman et al., 2014). Actually, epilepsy is a spectrum of brain disorders, so sometimes you will see the term *epilepsies*. People with **epilepsy** have recurrent seizures, but not all seizures are the result of epilepsy; temporary conditions such as high fever, infection, or withdrawal from drugs can also trigger seizures. Seizures take many forms and differ with regard to the length, frequency, and movements involved, but the two main types are *focal* and *generalized*.

Focal seizures originate in just one area of the brain. A person having a focal seizure may be conscious and experience a sudden feeling of joy, sadness, anger, or nausea, or sensations such as taste, smell, or movement in one part of the body. In other focal seizures, the individual may be in a dreamlike state and display repeated movements such as twitching, blinking, or walking in circles. These seizures are short, lasting only a minute or two (National Institute of Neurological Disorders and Stroke, 2016).

Generalized tonic-clonic seizures (once called *grand mal*) involve both sides of the brain. Most are accompanied by uncontrolled jerking movements that ordinarily last 2 to 5 minutes, possible loss of bowel or bladder control, and irregular breathing, followed by a deep sleep or coma. On regaining consciousness, the student may be very weary, confused, and in need of extra sleep. Most seizures can be controlled by medication.

If a student has a seizure accompanied by convulsions in class, the major danger is injury from striking a hard surface during the violent jerking. Immediately and gently lower the student to the floor, away from furniture or walls. Stay calm and reassure the rest of the class, asking them to remain in their seats. Do not try to restrain the child's movements; you can't stop the seizure once it starts. Loosen scarves, ties, or anything that might make breathing difficult. Turn the child's head gently to the side, and put a soft coat or blanket under his or her head. Never put anything in the student's mouth; it is NOT true that people having seizures can swallow their tongues. Don't attempt rescue breathing or CPR unless the student does not start breathing again after the seizure stops. Stay with the student until he or she recovers—about 5 to 20 minutes. Don't give water, pills, or food until the student is fully alert. Find out from the student's parents how they deal with seizures. If one seizure follows another and the student does not regain consciousness in between, if the student is pregnant or has a medical ID that does not say "epilepsy, seizure disorder," if there are signs of injury, or if the seizure goes on for more than 5 minutes, get medical help right away (Friend & Bursuck, 2019). (See <http://www.epilepsy.com/> and search "first aid" for more guidance.)

Not all seizures are dramatic. Sometimes the student just loses contact briefly. The student may stare, fail to respond to questions, drop objects, and miss what has been happening for 1 to 30 seconds. These were once called *petit mal*, but they are now referred to as **absence seizures**—a type of generalized seizure involving both sides of the brain. Such seizures can easily go undetected. If a child in your class appears to daydream frequently, does not seem to know what is going on at times, or cannot remember what has just happened when you ask, you should consult the school psychologist or nurse. The major problem for students with absence seizures is that they miss the continuity of the class interaction because these seizures can occur as often as 100 times a day. If their seizures are frequent, students will find the lessons confusing. Talk with these students to make sure they are able to follow and understand the lesson. Be prepared to repeat yourself periodically.

Epilepsy Disorder marked by seizures and caused by abnormal electrical discharges in the brain.

Focal seizure A seizure originating in just one area of the brain lasting only a minute or two. The person may experience a sudden feeling of joy, sadness, anger, or nausea, or sensations such as taste, smell, or movement in one part of the body.

Generalized tonic-clonic seizure A seizure involving a large portion of the brain.

Absence seizure A seizure involving only a small part of the brain that causes a child to lose contact briefly with ongoing events—short lapses of consciousness.

OTHER SERIOUS HEALTH CONCERNS: ASTHMA, SICKLE CELL DISEASE, AND DIABETES. Many other health problems affect students' learning, in great part because the students miss school, which leads to lost instructional time and missed opportunities for friendships. Asthma is a chronic lung condition affecting about 7 million children in America; it is more common for students in poverty. About 25% of the students identified with health impairments have asthma or allergies, so you may have one or two students with asthma in every class. Sickle cell disease is an inherited disorder that occurs most often in African American students, but also in individuals with Greek or Italian heritage. Students with sickle cell disease may be tired, have mild to severe pain, repeated infections,

and sometimes kidney failure (Friend & Bursuck, 2019). (For more information, see www.nhlbi.nih.gov and search for the specific health issues.)

Type 2 diabetes is a chronic disease that affects the way the body metabolizes sugar (glucose) and can damage almost every major organ in the body, including the heart, blood vessels, nerves, eyes, and kidneys if not treated (Mayo Clinic, 2009). For most children, Type 2 diabetes can be managed, or prevented altogether, by eating healthy foods, being physically active, and maintaining a healthy body weight. When diet and exercise modifications are not enough, children will need medications, such as insulin, to manage their blood sugar (Rosenberg et al., 2011; Werts, Culatta, & Tompkins, 2007).

With all health conditions, teachers need to talk to parents to find out how the problems are handled, what the signs are that a dangerous situation might be developing, and what resources are available for the student. Keep records of any incidents. They may be useful in the student's medical diagnosis and treatment.

STUDENTS WITH VISION IMPAIRMENTS. In the United States, about 1 in every 2,500 children and adolescents ages 6 to 17 (.04%) has a visual disability so serious that special services are needed. Most members of this group are classified as having **low vision**—they can read with the aid of a magnifying glass, large-print books, or other aids, though some may benefit from using Braille. Students who are **legally blind** have a visual acuity of 20/200 or less after correction (they can see at 20 feet what a person with normal vision can see at 200 feet) and/or have severely restricted peripheral vision (Erickson, Lee, & von Schrader, 2013; Hallahan et al., 2015).

Students who have difficulty seeing often hold books either very close to or very far from their eyes. They may squint, rub their eyes frequently, close one eye, blink often, or say that their eyes burn or itch. After close-up work, they may complain that they are dizzy, have a headache, or are sick to their stomach. The eyes may actually be swollen, red, or encrusted. Students with vision problems may misread material on the whiteboard or chalkboard, describe their vision as being blurred, be very sensitive to light, or hold their heads at an odd angle. They may become irritable when they have to do deskwork or lose interest if they have to follow an activity that is taking place across the room (Hallahan et al., 2015; N. Hunt & Marshall, 2002). Any of these signs should be reported to a qualified school professional.

Special materials and equipment that help these students to function in general education classrooms include large-print books; software that converts printed material to speech or to Braille; personal organizers that have talking appointment books or address books; special calculators; an abacus; three-dimensional maps, charts, and models; and special measuring devices. For students with visual problems, the quality of the print is often more important than the size, so watch out for hard-to-read handouts and blurry copies. Also, when you write or project something on the board, be sure to read it aloud.

The arrangement of the room is important as well. Students with visual problems need to know where things are, so consistency matters—a place for everything and everything in its place. Leave plenty of space for moving around the room, and make sure to monitor possible obstacles and safety hazards such as trash cans in aisles and open cabinet doors. If you rearrange the room, give students with visual problems a chance to learn the new layout. Also make sure these students have a buddy for fire drills or other emergencies (Friend & Bursuck, 2019).

STUDENTS WHO ARE DEAF. You will hear the term *hearing impaired* used to describe these students, but the Deaf community and researchers object to this label, so I will use their preferred terms, *deaf* and *hard of hearing*. The number of deaf students has been declining over the past three decades (now about 1 out of every 1,000 students ages 6 to 17), with over one-third of these students coming from Spanish-speaking homes. The consequences of hearing difficulties for learning are serious, especially when combined with learning in a second language.

By the way, the capital “D” in Deaf community in the first paragraph of this section refers to a group of people who want to be recognized as having their own culture and

Low vision Vision limited to close objects.

Legally blind Seeing at 20 feet what a person with normal vision would see at 200 feet and/or having severely restricted peripheral vision.

language, much like any other language-minority group. This is an example of identity-first language, described at the beginning of this chapter, to honor the wishes of the community (Hallahan et al., 2015). From this perspective, people who are deaf are part of a different culture with a different language, values, social institutions, and literature. N. Hunt and Marshall (2002) quote one deaf professional: “How would women like to be referred to as male-impaired, or whites like to be called black-impaired? I’m not impaired; I’m deaf!” (p. 348). From this perspective, a goal is to help deaf children become bilingual and bicultural, to enable them to function effectively in both cultures. Technological innovations and the many avenues of communication through the Internet have expanded communication possibilities for all people.

Signs of hearing problems are include turning one ear toward the speaker, favoring one ear in conversation, or misunderstanding conversation when the speaker’s face cannot be seen. Other indications are not following directions, seeming distracted or confused at times, frequently asking people to repeat what they have said, mispronouncing new words or names, and being reluctant to participate in class discussions. Take note particularly of students who have frequent earaches, sinus infections, or allergies.

In the past, educators have debated whether oral or manual approaches are better for children who are deaf or hard of hearing. Oral approaches involve speech reading (also called *lip reading*) and training students to use whatever limited hearing they may have. Manual approaches include sign language and finger spelling. Sign languages such as American Sign Language (ASL) are true, complete, and grammatically complex languages. Research indicates that children who learn both oral and manual methods of communicating perform better in academic subjects and are more socially mature than students who are exposed only to oral methods. Today, the trend is to combine both approaches. However, some members of the Deaf community prefer emphasizing ASL as their first language (Hallahan et al., 2015).

Autism Spectrum Disorders and Asperger Syndrome

You may be familiar with the term *autism*. In 1990 **autism** was added to the IDEA list of disabilities qualifying for special services. It is defined as “a developmental disability significantly affecting verbal and nonverbal communication and social interaction, generally evident before age three, that adversely affect the child’s educational performance” (34 *Federal Code of Regulations* § 300.7). I will use the term preferred by professionals in the field, **autism spectrum disorders**, to emphasize that autism includes a range of disorders from mild to major. You might also hear the term **pervasive developmental disorder (PDD)**, especially if you are talking with medical professionals. Estimates of the number of children with autism vary greatly but are increasing dramatically. Based on surveys and interviews with parents, The Centers for Disease Control found that 1 in every 45 children ages 3 to 17 have been diagnosed with autism—about 75% were boys (CDC, 2015).

Students with autism spectrum disorders may have many characteristics that impact learning in classrooms. They may have difficulty forming connections with others, may avoid eye contact, or may not share feelings such as enjoyment or interest in others. Communication is impaired. About half of these students are nonverbal; they have no or very few language skills. Others make up their own language. They may obsessively insist on regularity and sameness in their environments and have difficulty thinking imaginatively; change is very disturbing. They may repeat behaviors or gestures and have very restricted interests, watching the same DVD over and over, for example, or wanting to learn only about dinosaurs, trains, or hurricanes. They may be very sensitive to light, sound, touch, or other sensory information. Sounds may be painful, for example, or the slight flickering of fluorescent lights may seem like constant bursts, causing severe headaches. They may be able to memorize words or steps in problem solving, but not use them appropriately or become very confused when the situation changes or questions are asked in a different way (Franklin, 2007; Friend, 2014; Gunn & Delafield-Butt, 2015).

Asperger syndrome is one of the disabilities included in the autism spectrum. Children with Asperger syndrome have many of the characteristics just described, especially fixations and restricted interests, but they have the greatest trouble with social relations.

Autism/Autism spectrum disorders Developmental disability significantly affecting verbal and nonverbal communication and social interaction, generally evident before age 3 and ranging from mild to major.

Pervasive developmental disorder (PDD) A term favored by the medical community to describe autism spectrum disorders.

Language is less affected. Their speech may be fluent but unusual, mixing up pronouns of “I” and “you,” for example. Many students with autism also have moderate-to-severe intellectual disabilities, but those with Asperger syndrome usually have average-to-above-average intelligence. In 2013, the American Psychiatric Association eliminated the term *Asperger syndrome* and replaced it with the diagnosis of *high functioning autism spectrum disorder*, so you may hear that term as well (Friend, 2014; Gunn & Delafield-Butt, 2015).

INTERVENTIONS. Early and intense interventions that focus on communications and social relations are particularly important for children with autism spectrum disorders. Without interventions, behaviors such as poor eye contact and odd-seeming mannerisms tend to increase over time (Matson et al., 2007). As they move into elementary school, some of these students will be in inclusive settings, others will be in specialized classes, and many will be in some combination of these two. Collaboration among teachers and the family is particularly important. Strategies such as providing smaller classes, offering structured environments, finding a class “buddy” to give support, maintaining a safe “home base” for times of stress, ensuring consistency in instruction and transition routines, implementing assistive technologies, and using visuals may be part of a collaborative plan.

Because many students with autism spectrum disorders have intense interests, these interests can be incorporated into class activities. For example, in a lesson on writing complete sentences, students who are fascinated with trains can write sentences about trains. Students who love searching the Internet can do research on an assigned topic and contribute to the class learning. Perhaps the student’s interest can be folded into interdisciplinary projects. If it is really difficult to incorporate the student’s interest into the curriculum, focusing on the interest can be a reward for completing assignments on other topics—an “if-then” agreement. In fact, all of these are good teaching strategies for every student (Friend, 2014; Gunn & Delafield-Butt, 2015; Harrower & Dunlap, 2001). With older students, video-based instruction, such as showing the student a video of someone performing a target skill or behavior and then encouraging the student to imitate and practice that skill, has proved effective. Through adolescence and the transition to adulthood, instruction and guidance in life, work, and social skills are important educational goals (de Bruin et al., 2013).

Response to Intervention

One of the problems for students with serious learning problems is that they have to struggle through the early grades, often falling farther and farther behind, until they are identified, assessed, qualified for an IDEA category, receive an IEP, and finally get appropriate help. This has been called the “wait to fail” model. The reauthorization of IDEA in 2004 gave educators a new option for assessing and educating students who might have serious learning problems. The process is called **response to intervention (RtI)**. The main goal of RtI is to make sure students get appropriate research-based instruction and support as soon as possible, in kindergarten if they need it, before they have fallen too far behind. A second goal is to make sure teachers are systematic in documenting the interventions they have tried with these students and describing how well each intervention worked. In addition, instead of using the discrepancy between IQ scores and student achievement to identify students with learning disabilities, educators can now use RtI criteria to determine who needs more intensive learning support (Klinger & Orosco, 2010; Scruggs & Mastropieri, 2013). However, this last use of RtI has been criticized for not being a valid or reliable way of assessing students with learning disabilities because it does not provide a comprehensive and thorough picture of the student’s strengths and weaknesses, including documenting other problems that might be present (Reynolds & Shaywitz, 2009).

One common way of reaching these RtI goals is a *three-tiered system*. The first tier is to use a strong, well-researched way of teaching all students (we will look at these kinds of approaches in Chapters 13 and 14). For example, teachers might design ways to

MyLab Education
Video Example 4.5

In this video, two teachers discuss their experiences teaching children with autism. As you watch, note how they focus on the unique and special characteristics of each individual child.

Response to intervention (RTI) A process to make sure students get appropriate research-based instruction and support as soon as possible and that teachers are systematic in documenting the interventions they have tried with these students so they can use this information in planning instruction.

FIGURE 4.5

THREE TIERS OF SERVICE AND SUPPORT IN RESPONSE TO INTERVENTION

Source: Based on Friend, M. P., & Bursuck, W. D. (2019). *Including Students with Special Needs: A Practical Guide for Classroom Teachers* (8th ed.). Boston, MA: Pearson Education.

incorporate every student's individual interests into class assignments, thus more effectively engaging all their students, including those with autism spectrum disorders and those with ADHD. A teacher who is concerned about the behavior of one or several students might work with the school psychologist to develop a class-wide behavior management program, and then document which students do or do not respond to the new program.

Students who are struggling in the Tier 1 curriculum, as identified by ongoing quality classroom assessments, are moved to the second tier and receive extra support. About 15% of students will need to be moved to Tier 2 for individual or group work with a specialist, social skills instruction, or counseling, for example. To be effective at this level, instruction must be intensive and focused on the student's needs. If some students still make limited progress, usually about 5% of students, they move to Tier 3 for additional one-to-one intensive help and perhaps a special needs assessment (Denton et al., 2013; Lonigan & Phillips, 2016; Sullivan, & Castro-Villarreal, 2013). Figure 4.5 summarizes the tiers.

The RtI approach has at least two advantages. First, students get extra help right away. Second, if the students reach the third stage of RtI, the information gained based on the students' responses to the different interventions at Tier 1 and Tier 2 can be used for IEP planning. In order to achieve these advantages, general education teachers, particularly in the early grades, must be able to teach and assess using high-quality, research-based approaches.

TABLE 4.11 • Making a Referral

1. Contact the student's parents. It is very important that you discuss the student's problems with the parents *before* you refer.
2. Before making a referral, check *all* the student's school records. Has the student ever:
 - had a psychological evaluation?
 - qualified for special services?
 - been included in other special programs (e.g., for disadvantaged children; speech or language therapy)?
 - scored far below average on standardized tests?
 - been retained?

Do the records indicate:

 - good progress in some areas, poor progress in others?
 - any physical or medical problem?
 - that the student is taking medication?
3. Talk to the student's other teachers and professional support personnel about your concern for the student. Have other teachers also had difficulty with the student? Have they found ways of dealing successfully with the student? Document the strategies that you have used in your class to meet the student's educational needs. Your documentation will be useful as evidence that will be helpful to or be required by the committee of professionals who will evaluate the student. Demonstrate your concern by keeping written records. Your notes should include items such as:
 - exactly what you are concerned about
 - why you are concerned about it
 - dates, places, and times you have observed the problem
 - precisely what you have done to try to resolve the problem
 - who, if anyone, helped you devise the plans or strategies you have used
 - evidence that the strategies have been successful or unsuccessful

Remember that you should refer a student only if you can make a convincing case that the student probably cannot be served appropriately without special services. Referral begins a time-consuming, costly, and stressful process that is potentially damaging to the student and has many legal ramifications.

Even with intensive, high-quality Tier 3 interventions, some students may continue to struggle and will need extended support, instruction, and practice (Denton et al., 2013). Thus far, RtI has been most successful for younger students and with basic processes such as letter-sound connections in learning to read. We don't know as much about how students with learning challenges respond to more sophisticated learning tasks. Also, there is quite a bit of variability in the ways individual schools define evidence-based practices, lack of response to teaching, and progress monitoring (Scruggs & Mastropieri, 2013; Sullivan, & Castro-Villarreal, 2013). For more information on RtI, go to the Web site for the National Center on Response to Intervention (rti4success.org/).

This has been a brief, selective look at the needs of children. If you decide that students in your class might benefit from special services of any kind, the first step is making a referral. How would you begin? Table 4.11 guides you through the referral process. In Chapter 14, when we discuss differentiated teaching, we will look at more ways to reach all your students.

We end the chapter with another group of students who have special needs but are not covered by IDEA or Section 504—students who are highly intelligent or talented.

STUDENTS WHO ARE GIFTED AND TALENTED

Consider this situation, a true story.

Latoya was already an advanced reader when she entered 1st grade in a large urban school district. Her teacher noticed the challenging chapter books Latoya brought to school and read with little effort. After administering a reading assessment, the school's reading consultant confirmed that Latoya was reading at the 5th grade level. Latoya's parents reported with pride that she had started to read independently when she was 3 years old and "had read every book she could get her hands on." (Reis et al., 2002, p. 32)

In her struggling urban school, Latoya received no particular accommodations, and by fifth grade, she was still reading at just above the fifth-grade level. Her fifth-grade teacher had no idea that Latoya had ever been an advanced reader.

Here is another true story:

Alex Wade's field is linguistics. In his search for the perfect language—and "annoyed," he says, with Esperanto—he has created 10 languages and 30 or 40 alphabets, including one language without verbs, just for the challenge. He's taking courses at the University of Nevada, Reno, in Basque, linguistics, and microbiology (because he also has a talent for science). . . . Alex is 13. (Kronholz, 2011, p. 1)

Latoya and Alex are not alone. They are part of a group with special needs that is often overlooked by the schools: students who are **gifted and talented**. There is growing recognition that students who are gifted are being poorly served by most public schools; in addition, underachievement has become a serious problem (Callahan et al., 2015; Snyder, Malin, Dent, & Linnenbrink-Garcia, 2014). For example, a study by the Jack Kent Cooke Foundation found that 20 states did not allow students to start kindergarten early, even if they were reading at a high level—a recipe for boredom and ultimately underachievement. Many states had no policy or left the decision to the local districts, and only 11 states specifically allowed early admission (Plucker, Gianola, Healey, Arndt, & Wang, 2015). What would that mean for students like Latoya and Alex (Kronholz, 2011)?

Who Are These Students?

There are many definitions of *gifted* because individuals can have many different gifts. Remember that Gardner (2003) identified 9 separate "intelligences," and Sternberg (1997) suggests a triarchic model. Renzulli (2011; Reis & Renzulli, 2009, 2010) have a different three-part conception of giftedness: above-average general ability, a high level of creativity, and a high level of task commitment or motivation to achieve. The NAGC defines gifted individuals as

those who demonstrate outstanding levels of aptitude (defined as an exceptional ability to reason and learn) or competence (documented performance or achievement in top 10% or rarer) in one or more domains. Domains include any structured area of activity with its own symbol system (e.g., mathematics, music, language) and/or set of sensorimotor skills (e.g., painting, dance, sports). (NAGC, 2016)

To make matters even more complicated, almost every state in the United States has its own definition—check out your state by going to <http://www.nagc.org/> and searching for "definitions of giftedness."

Children who are truly gifted do more than learn quickly with little effort. The work of students who are gifted is original, extremely advanced for their age, and potentially of lasting importance. These children may read fluently with little instruction by age 3 or 4. They may play a musical instrument like a skillful adult, turn a visit to the grocery store into a mathematical puzzle, and become fascinated with algebra when their friends are having trouble with simple addition (Winner, 2000). Recent conceptions widen the view of giftedness to include attention to the children's culture, language, and special needs (NAGC, 2013). These newer conceptions are more likely to identify children like Latoya.

Gifted and talented Students who demonstrate outstanding aptitudes and competencies in one or more of many domains.

WHAT IS THE ORIGIN OF THESE GIFTS? Studies of prodigies and geniuses in many fields document that deep and prolonged practice is necessary to achieve at the highest levels. For example, it took Newton 20 years to move from his first ideas to his ultimate contribution (Howe, Davidson, & Sloboda, 1998; Winner, 2000). I remember listening to the early reports of Bloom's study of world-class concert pianists, sculptors, Olympic swimmers, research neurologists, mathematicians, and tennis champions (B. S. Bloom, 1982). To study talent in tennis, Bloom's research team interviewed the top tennis players in the world, their coaches, parents, siblings, and friends. One coach said that he would make a suggestion, and a few days later the young athlete would have mastered the move. Then the parents told how the child had practiced that move for hours on end after getting the coach's tip. So, focused, intense practice plays a role. Also, the families of prodigies tend to be child-centered and to devote hours to supporting the development of their child's gifts. Bloom's research team described tremendous sacrifices made by families: rising before dawn to drive their child to a swimming coach or piano teacher in another city, working two jobs, or even moving the whole family to another part of the country to find the best teachers or coaches. The children responded to the family's sacrifices by working harder, and the families responded to the child's hard work by sacrificing more—an upward spiral of investment and achievement.

But hard work will never make me a world-class tennis player or a Newton. There is a role for nature as well. The children Bloom studied showed early and clear talent in the areas they later developed. As children, great sculptors were constantly drawing and great mathematicians were fascinated with dials, gears, and gauges. Parents' investments in their children came after the children showed early high-level achievement (Winner, 2000, 2003). Recent research suggests that children who are gifted, at least those with extraordinary abilities in mathematics, music, and visual arts, may have unusual brain organization—which can have both advantages and disadvantages. Giftedness in mathematics, music, and visual arts appears to be associated with superior visual-spatial abilities and enhanced development of the right side of the brain. Children with these gifts are more likely to have left-hand dominance but also to have language related-problems.

WHAT PROBLEMS DO STUDENTS WHO ARE GIFTED FACE? Even though longitudinal studies of academically gifted students indicate they are better adjusted and more successful on average as adults than their nongifted peers (Holahan & Sears, 1995; Jolly, 2008; Terman, Baldwin, & Bronson, 1925; Terman & Oden, 1947, 1959), it would be incorrect to say that every student who is gifted is superior in adjustment and emotional health. In fact, adolescents who are gifted, especially girls, are more likely to be depressed, and both girls and boys may be bored, frustrated, and isolated. Schoolmates may be consumed with baseball or worried about failing math, while the child with gifts and talents is fascinated with Mozart, focused on a social issue, or totally absorbed in computers, drama, or geology. Children who are gifted may be impatient with friends, parents, and even teachers who do not share their interests or abilities (Woolfolk & Perry, 2015). One researcher asked 13,000 gifted students from seven states to name one word for their experiences. The most commonly used word was "waiting." "Waiting for teachers to move ahead, waiting for classmates to catch up, waiting to learn something new—always waiting" (Kronholz, 2011, p. 3).

Because their language is well developed, students who are gifted may be seen as show-offs when they are simply expressing themselves. They are sensitive to the expectations and feelings of others, so these students may be very vulnerable to criticisms and taunts. Their keen sense of humor and verbal skills can be used as weapons against teachers and other students or as a defense to diffuse the pain of being bullied (Hardman et al., 2014). Because they are goal directed and focused, they may seem stubborn and uncooperative. For example, Marilyn Friend and William Bursuck (2015) describe Esteban, an eighth grader whose response about everything to everyone—peers, parents, and teachers—was "I already know that," which was usually true and often irritating. Adjustment problems seem to be greatest for the students among the most highly gifted, those in the highest range of academic ability (e.g., above 180 IQ). The chance of any teacher encountering a student in this highest IQ range is only about 1 in 80 over an entire 40-year career—but what if such a student walks into your class (Kronholz, 2011)?

Identifying Students Who Are Gifted and Talented

Identifying children who are gifted is not always easy. Many parents provide early educational experiences for their children. In middle and high school, some very able students deliberately earn lower grades, making their abilities even harder to recognize. Girls are especially likely to hide their abilities (Woolfolk & Perry, 2015).

RECOGNIZING GIFTS AND TALENTS. In general, teachers make reasonable, but not perfect predictions of students' academic achievement (Südkamp, Kaiser, & Möller, 2012). Table 4.12 lists the characteristics to notice to make better identifications.

Certainly, the students described at the beginning of this section—Latoya who read so early and Alex with his intense interests and creativity in inventing languages, had some of these characteristics. In addition, students who are gifted may prefer to work alone, have a keen sense of justice and fairness, be energetic and intense, form strong commitments to friends—often older students—and struggle with perfectionism.

Group achievement and intelligence tests tend to underestimate the IQs of very bright children. Group tests may be appropriate for screening, but they are not appropriate for making placement decisions. Some evidence suggests that using individual IQ tests such

TABLE 4.12 • Characteristics to Observe in Identifying Students Who Are Gifted

READING BEHAVIORS
• Has early knowledge of the alphabet • Often reads early or unlocks the reading process quickly and sometimes idiosyncratically • Reads with expression • Has a high interest in reading; reads voraciously
WRITING BEHAVIORS
• Displays early ability to make written sound–symbol correspondence • Exhibits fluency and elaboration in story writing • Uses advanced sentence structure and patterns • May show an interest in adult topics for writing, such as the state of the environment, death, war, and so on • Writes on a topic or story for an extended period of time • Generates many writing ideas, often of a divergent nature • Uses precise, descriptive language to evoke an image
SPEAKING BEHAVIORS
• Learns to speak early • Has a high-receptive vocabulary • Uses advanced sentence structure • Uses similes, metaphors, and analogies in daily conversation • Exhibits highly verbal behavior in speech (i.e., talks a lot, speaks rapidly, articulates well) • Enjoys acting out story events and situations
MATHEMATICAL BEHAVIORS
• Has early curiosity and understanding about the quantitative aspects of things • Is able to think logically and symbolically about quantitative and spatial relationships • Perceives and generalizes about mathematical patterns, structures, relations, and operations • Reasons analytically, deductively, and inductively • Abbreviates mathematical reasoning to find rational, economical solutions • Displays flexibility and reversibility of mental processes in mathematical activity • Remembers mathematical symbols, relationships, proofs, methods of solution, and so forth • Transfers learning to novel situations and solutions • Displays energy and persistence in solving mathematical problems • Has a mathematical perception of the world

as the Wechsler Intelligence Scale for Children V (WISC-V, Wechsler, 2004), which include evaluations of verbal comprehension and working memory, are the best predictors of achievement in reading and math for students who are gifted (E. W. Rowe, Kingsley, & Thompson, 2010). Many psychologists recommend a case study approach. This means gathering many kinds of information about the student in different contexts: test scores, grades, examples of work, projects and portfolios, letters or ratings from community or church members, self-ratings, nominations from teachers or peers, and so on (Renzulli & Reis, 2003). Especially for recognizing artistic talent, experts in the field can be called in to judge the merits of a child's creations. Science projects, exhibitions, performances, auditions, and interviews are all possibilities. Creativity tests and tests of self-regulation skills may identify some children not picked up by other measures, particularly minority students who may be at a disadvantage on the other types of tests (Grigorenko et al., 2009). Given the different definitions and wide-ranging procedures for identifying students who are gifted, between 1% and 25% of students in each state in the United States are served in programs for students who are gifted, or about 3 million total (Friend, 2014).

Remember, students with remarkable abilities in one area may have much less impressive abilities in others. And up to 180,000 students in American schools may be gifted *and* have learning disabilities. In addition, two other groups are underrepresented in education programs for students who are gifted: girls and students living in poverty (Stormont, Stebbins, & Holliday, 2001). See Table 4.13 for ideas about identifying and supporting these students.

Teaching Students with Gifts and Talents

Some educators believe that students who are gifted should be *accelerated*—moved quickly through the grades or through particular subjects. Other educators prefer

TABLE 4.13 • **Recognizing and Supporting All Students with Gifts and Talents—Especially Girls and Students Living in Poverty**

RECOGNIZING STUDENTS WHO ARE GIFTED AND HAVE LEARNING DISABILITIES
Here are some ideas for supporting students who are gifted and have learning disabilities (McCoach, Kehle, Bray, & Siegle, 2001): • Identify these students by looking longitudinally at achievement. • Remediate skill deficits, but also identify and develop talents and strengths. • Provide emotional support; it is important for all students, but especially for this group. • Help students learn to compensate directly for their learning problems, and assist them in “tuning in” to their own strengths and difficulties.
RECOGNIZING GIFTS IN GIRLS
As young girls develop their identities in adolescence, they often reject being labeled as gifted—being accepted and popular and “fitting in” may become more important than achievement (Basow & Rubin, 1999; Stormont et al., 2001). How can teachers reach girls who are gifted? • Notice when girls’ test scores seem to decline in middle or high school. • Encourage assertiveness, achievement, high goals, and demanding work from all students. • Provide models of achievement through speakers, internships, or readings. • Look for and support gifts in arenas other than academic achievement.
RECOGNIZING STUDENTS WHO ARE GIFTED WHO LIVE IN POVERTY
Health problems, lack of resources, homelessness, fears about safety and survival, frequent moves, and responsibilities for the care of other family members all make achievement in school more difficult. To identify students with gifts: • Use alternative assessment, teacher nomination, and creativity tests. • Be sensitive to cultural differences in values about cooperative or solitary achievement (Ford, 2000). • Use multicultural strategies to encourage both achievement and the development of racial identities.

enrichment—giving the students additional, more sophisticated, and more thought-provoking work but keeping them with their age-mates in school. Both may be appropriate (Torrance, 1986). One way of doing this is through *curriculum compacting*—assessing students’ knowledge of the material in the instructional unit, then teaching only for those goals not yet reached (Reis & Renzulli, 2004). Using curriculum compacting, teachers may be able to eliminate about half of the usual curriculum content for some students who are gifted without any loss of learning. The time saved can be used for learning goals that include enrichment, sophistication, and novelty (Werts et al., 2007).

ACCELERATION. Many people object to acceleration, but most careful studies indicate that students who are truly gifted who begin primary, elementary, middle, or high school, college, or even graduate school early do as well as, and usually better than, students who are not gifted who are progressing at the standard pace. You may remember from Chapter 1 that students who were mathematically talented and who skipped grades in elementary or secondary school were more likely to go on to earn advanced degrees and publish widely cited articles in scientific journals (Park, Lubinski, & Benbow, 2013). Social and emotional adjustment does not appear to be impaired either. Students who are gifted tend to prefer the company of older playmates (G. A. Davis, Rimm, & Siegle, 2011; Plucker et al., 2015).

An alternative to skipping grades is to accelerate students in one or two particular subjects or to allow concurrent enrollment in advanced placement or college courses, but keep them with peers for the rest of the time. For students who are extremely advanced intellectually (e.g., those scoring 160 or higher on an individual intelligence test), the only practical solution likely is to accelerate their education (G. A. Davis et al., 2011; Kronholz, 2011).

METHODS AND STRATEGIES. Teaching methods for students who are gifted should encourage abstract thinking (formal-operational thought), creativity, reading of high-level and original texts, and independence, not just the learning of greater quantities of facts. The CLEAR model has been successful in teaching gifted students because it embodies these qualities (Callahan et al., 2015). CLEAR stands for **C**ontinual **F**ormative **A**ssessment (Chapter 15), **C**lear **L**earning **G**oals (Chapter 14), **D**ata-**D**riven **L**earning **E**xperiences (Chapter 10), **A**uthentic **P**roducts (Chapter 10), and a **R**ich **C**urriculum. Students pursue important goals by developing and carrying out projects on personally chosen topics using the methods and tools of professionals in the field. In the process, they move beyond factual knowledge to grasp the big ideas, skills, advanced vocabulary, ethical issues, and essential knowledge in a discipline. For more information, see <http://nrcgtuva.org/CLEARcurriculum.html>.

In working with students who are gifted and talented, a teacher must be imaginative, flexible, tolerant, and unthreatened by the capabilities of these students. The teacher must ask: What do these children need most? What are they ready to learn? Who can help me to challenge them? Challenge and support are critical for all students. But challenging students who know more than anyone else in the school about history or music or science or math can be a challenge! Answers might come from faculty members at nearby colleges, retired professionals, books, museums, the Internet, or older students. Strategies might be as simple as letting the child do math with the next grade. Other options are summer institutes; courses at nearby colleges; classes with local artists, musicians, or dancers; independent research projects; selected classes in high school for younger students; honors classes; and special-interest clubs (Rosenberg, Westling, & McLeskey, 2011).

In the midst of providing challenge, don’t forget the support. We all have seen the ugly sights of parents, coaches, or teachers forcing the joy out of their talented students by demanding practice and perfection beyond the child’s interest. Just as we should not force children to stop investing in their talent (“Oh, Michelangelo, quit fooling with those sketches and go outside and play”), we also should avoid destroying intrinsic motivation with heavy doses of pressure and external rewards.

▼ SUMMARY

Intelligence (pp. 150–161)

What are the advantages of and problems with labels? Labels and diagnostic classifications can easily become both stigmas and self-fulfilling prophecies, but they can also open doors to special programs and help teachers develop appropriate instructional strategies.

What is person-first language? Person-first language (“students with intellectual disabilities,” “students placed at risk,” etc.) is an alternative to labels that describe a complex person with one or two words, implying that the condition labeled is the most important aspect of the person. Identity-first language is preferred by some individuals, including members of the deaf community.

Distinguish between a disability and a handicap. A disability is an inability to do something specific such as see or walk. A handicap is a disadvantage in certain situations. Some disabilities lead to handicaps, but not in all contexts. Teachers must avoid imposing handicaps on learners with disabilities.

What is *g*? Spearman suggested there is one mental attribute, which he called *g*, or general intelligence, that is used to perform any cognitive test, but that each test also requires some specific abilities in addition to *g*. A current version of the general plus specific abilities theory is Carroll’s work identifying a few broad abilities (e.g., learning and memory, visual perception, verbal fluency) and at least 70 specific abilities. Fluid and crystallized intelligence are two of the broad abilities identified in most research.

What is Gardner’s view of intelligence and his position on *g*? Gardner contends that there are several separate intelligences: linguistic, musical, spatial, logical-mathematical, bodily-kinesthetic, interpersonal, intrapersonal, naturalist, and perhaps existential. Gardner does not deny the existence of *g*, but questions how useful *g* is as an explanation for human achievements.

What are the elements in Sternberg’s theory of intelligence? Successful intelligence requires three skills or ways of thinking: analytic, creative, and practical. *Analytic skills* involve evaluating, analyzing, judging, comparing, and contrasting to deal with relatively familiar problems. *Creative/experiential* intelligence involves coping with new experiences through insight and automaticity. *Practical/contextual* intelligence involves choosing to live and work in a context where success is likely, adapting to that context, and reshaping it if necessary. Practical intelligence is made up mostly of action-oriented tacit knowledge learned during everyday life.

How is intelligence measured, and what does an IQ score mean? Intelligence is measured through individual tests (Stanford-Binet, Wechsler, etc.) and group tests (Otis-Lennon School Abilities Tests, Slosson Intelligence Test, Raven Progressive Matrices, Naglieri Nonverbal Ability Test—Multiform, Differential Abilities Scales, Wide Range Intelligence Test, etc.). Compared to an individual test, a group test is much less likely to yield an accurate picture of any one person’s abilities. The average score is 100. About 68% of the general population will earn IQ scores between 85 and 115. Only about 16% of the population will receive scores below 85, and another 16% will have scores above 115. These figures hold true for

White, native-born Americans whose first language is Standard English. Intelligence tests predict success in school but is less predictive of success in life when level of education is taken into account.

What is the Flynn effect, and what are its implications? Since the early 1900s, IQ scores have been rising. Some explanations include better nutrition and medical care for children and parents, increasing complexity in the environment that stimulates abstract thinking, smaller families who give more attention to their children, increased literacy of parents (particularly better-educated mothers), more and better schooling, and better preparation for taking tests.

Are there sex differences in cognitive abilities? Girls seem to be better on verbal tests, especially when writing is involved. Males seem to be superior on tasks that require mental rotation of objects. The scores of males tend to be more variable in general, so there are more males than females with very high and very low scores on tests. There are two cautions, however. These sex differences generally are small. Also, in most studies, race and ethnicity are not taken into account.

Creativity: What It Is and Why It Matters (pp. 161–167)

What is creativity, and how is it assessed? Creativity is a process that involves independently restructuring problems to see things in new, imaginative ways. Creativity is difficult to measure, but tests of divergent thinking can assess originality, fluency, and flexibility. Fluency (the absolute number of answers) is the best measure of divergent thinking.

What can teachers do to support creativity in the classroom? Multicultural experiences appear to help students think flexibly and creatively. Teachers can encourage creativity in their interactions with students by accepting unusual, imaginative answers; questioning assumptions; modeling divergent thinking; using brainstorming; encouraging and celebrating fantasy and quirkiness, and tolerating dissent.

Learning Styles (pp. 167–169)

Distinguish between learning styles and learning preferences. Learning styles are the characteristic ways a person approaches learning and studying. Learning preferences are individual preferences for particular learning modes and environments.

Should teachers match instruction to individual learning styles? Results of research indicates that students do not learn more when they study in their preferred setting and manner. Many students would do better to develop new—and perhaps more effective—ways to learn.

What learning style distinctions are the most well supported by research? One distinction that is repeatedly found in research is Mayer’s visualizer–verbalizer dimension that has three facets: cognitive spatial ability (low or high), cognitive style (a visualizer vs. a verbalizer), and learning preference (a verbal learner vs. a visual learner). Teaching implications of these differences are not clear yet.

Individual Differences and the Law (pp. 169–173)

Describe the main legal requirements that pertain to students with disabilities. Beginning with Public Law 94–142 (1975) and continuing with many reauthorizations including IDEA, the Individuals with Disabilities Education Act (2004), the requirements for teaching students with disabilities have been spelled out. Each learner or student with special needs (zero reject) should be educated in the least restrictive environment (LRE) according to an individualized education program (IEP). The laws also protect the rights of students with special needs and their parents. In addition, Section 504 of the Vocational Rehabilitation Act of 1973 prevents discrimination against people with disabilities in any program that receives federal money, such as public schools. Through Section 504, all school-age children are ensured an equal opportunity to participate in school activities. The definition of disability is broad in Section 504 and in the Americans with Disabilities Act.

Students with Learning Challenges (pp. 173–193)

What does research in neuroscience tell us about learning problems? Studies of the brains of students with learning disabilities and with attention-deficit disorders show some differences in structure and activity compared to those of students without problems. Students with learning disabilities have problems in using the system of working memory that holds verbal and auditory information while you work with it. Because children with learning disabilities have trouble holding on to words and sounds, it is difficult for them to put the words together to comprehend the meaning of a sentence or to figure out what a math story problem is really asking about. Students with learning disabilities also may have difficulties retrieving needed information from long-term memory while transforming new incoming information, such as the next numbers to add. Important bits of information keep getting lost.

What is a learning disability? Specific learning disabilities are disorders in one or more of the basic psychological processes involved in understanding or using spoken or written language. Listening, speaking, reading, writing, reasoning, or mathematical abilities might be affected. These disorders are intrinsic to the individual, presumed to be the result of central nervous system dysfunction, and may occur across the life span. Students with learning disabilities may become victims of learned helplessness when they come to believe that they cannot control or improve their own learning and therefore cannot succeed. A focus on learning strategies often helps students with learning disabilities.

What is ADHD, and how is it handled in school? ADHD is the term used to describe individuals of any age with hyperactivity and attention difficulties. Use of medication to address ADHD is controversial but currently on the rise. For many students the medication has negative side effects. In addition, little is known about the long-term effects of drug therapy. And no evidence indicates that the drugs lead to improvement in academic learning or peer relationships. Approaches that combine motivational training with instruction in learning and memory strategies and behavior modification seem effective.

What are the most common communication disorders? Common communication disorders include speech impairments (articulation disorders, stuttering, and voicing problems) and

oral language disorders. If these problems are addressed early, great progress is possible.

What are the best approaches for students with emotional and behavioral disorders? Methods from applied behavior analysis and direct teaching of social skills are two useful approaches. Students also may respond to structure and organization in the environment, schedules, activities, and rules.

What are some warning signs of potential suicide? Students at risk of suicide may show changes in eating or sleeping habits, weight, grades, disposition, activity level, or interest in friends. They sometimes suddenly give away prized possessions such as iPads, games, clothing, or pets. They may seem depressed or hyperactive and may start missing school or quit doing work. It is especially dangerous if the student not only talks about suicide but also has a plan for carrying it out.

What defines intellectual disabilities? Before age 18, students must score below about 70 on a standard measure of intelligence and must have problems with adaptive behavior, day-to-day independent living, and social functioning. The AAIDD now recommends a classification scheme based on the amount of support that a person requires to function at his or her highest level. Support varies from intermittent (as needed during stressful times), to limited (consistent support, but time-limited, such as employment training), to extensive (daily care, such as living in a group home), to pervasive (constant, high-intensity care for all aspects of living).

How would you handle a seizure in class? Do not restrain the child's movements. Lower the child gently to the floor, away from furniture or walls. Move hard objects away. Turn the child's head gently to the side, put a soft coat or blanket under the student's head, and loosen any tight clothing. Never put anything in the student's mouth. Find out from the student's family how they deal with seizures. If one seizure follows another and the student does not regain consciousness in between, if the student is pregnant, or if the seizure goes on for more than 5 minutes, get medical help right away.

What are some signs of visual and hearing impairments? Holding books very close or far away, squinting, rubbing eyes, misreading the chalkboard, and holding the head at an odd angle are possible signs of visual problems. Signs of hearing problems are turning one ear toward the speaker, favoring one ear in conversation, or misunderstanding conversation when the speaker's face cannot be seen. Other indications include not following directions, seeming distracted or confused at times, frequently asking people to repeat what they have said, mispronouncing new words or names, and being reluctant to participate in class discussions.

How does autism differ from Asperger syndrome? Asperger syndrome is one of the autism spectrum disorders. Many students with autism also have moderate-to-severe intellectual disabilities, but those with Asperger syndrome usually have average-to-above-average intelligence and better language abilities than children with autism. There is a move today to replace the diagnosis of Asperger syndrome with the diagnosis *high functioning autism spectrum disorder*.

What Is Response to Intervention (RtI)? RtI is an approach to supporting students with learning problems as early as possible, not waiting for years to assess, identify, and plan a

program. One RtI process is a three-tiered system. The first tier is to use a strong, well-researched way of teaching all students. Students who do not do well with these methods are moved to the second tier and receive extra support and additional small-group instruction. If some students still make limited progress, they move to the third tier for one-to-one intensive help and perhaps a special needs assessment.

Students Who Are Gifted and Talented (pp. 194–198)

What are the characteristics of students who are gifted? Students who are truly gifted do more than learn quickly with little effort. The work of students who are gifted is original, extremely advanced for their age, and potentially of lasting importance. These children may read fluently with little instruction by age 3 or 4. They may play a musical instrument like a skillful adult and become fascinated with algebra when

their friends are having trouble with simple addition. Teachers should make special efforts to support underrepresented students who are gifted—girls, students who also have learning disabilities, and children living in poverty.

Is acceleration a useful approach with students who are gifted? Many people object to acceleration, but most careful studies indicate that students who are truly gifted who are accelerated do as well as and usually better than students who are not gifted who are progressing at the normal pace. Students who are gifted tend to prefer the company of older playmates and may be bored if kept with children their own age. Skipping grades may not be the best solution for a particular student, but for students who are extremely advanced intellectually (with a score of 160 or higher on an individual intelligence test), the only practical solution may be to accelerate their education.

▼ CONNECT AND EXTEND TO LICENSURE

MULTIPLE-CHOICE QUESTIONS

- At the age of six, when Conchita entered primary school in Spain, she had her intelligence quotient (IQ) tested. Her Wechsler Intelligence Scale for Children IV (WISC-IV) score indicated that she had an above-average intelligence. As expected, throughout her schooling, she performed well. Why was this an expected outcome for Conchita?
 - Her WISC-IV score predicted her success in school.
 - She received extra learning support at school in order to achieve better results.
 - Her parents' high expectations from Conchita resulted in this achievement.
 - Conchita wanted to perform well at school and, hence, she did.
- Jasmine is particularly sensitive to numbers and is able to handle advanced logical reasoning tasks. Ryan, on the other hand, knows multiple languages and has great command in each of them. Yi, however, is better at understanding the needs of others. Which of the following is true?
 - Multiple intelligence theory will regard Jasmine as the most intelligent person among them.
 - Jasmine has higher general intelligence, Ryan has higher crystallized intelligence, and Yi has better fluid intelligence.
 - Without other additional information, multiple intelligence theory will suggest that all of them are at least equally intelligent.
 - Triarchic theory of successful intelligence will label Jasmine as analytic, Ryan as creative, and Yi as practical.
- Bela is an eight-year old girl who was emotionally stable and had performed well in school. Her parents have recently divorced. Due to this, she has become a very anxious child. What can Bela's teacher do to help alleviate her anxiety in the classroom?
 - Her teacher could respect Bela's emotional state and leave her alone.
 - Her teacher could provide Bela with counseling regarding her anxiety.
 - Her teacher could tell the other children that Bela is anxious, and that they must be extra nice to her.
 - Her teacher could provide structure, organizational tools, and choices.
- Kemeul had a fourth-grade reading level when he was in the first grade in the Democratic Republic of the Congo. He had the same teacher from the first to the third grade, Ms. Mlambo. She was wary of appearing to favor him, hence, she did not provide any extra learning support to him. When he leaves the third grade, his reading level has stagnated. Why do you think Kemeul has not performed according to his gifted ability?
 - Ms. Mlambo shared her beliefs with her supervisors, and was informed that favoritism is frowned upon.
 - Gifted children such as Kemeul need the extra learning support from their teachers in order to achieve their potential.
 - Ms. Mlambo decided to only identify and build on the class's knowledge.
 - Ms. Mlambo was not aware that Kemeul was a gifted child.

CONSTRUCTED-RESPONSE QUESTIONS

Case

Shaqir, a seven-year-old student in Ms. Qisha's class, displayed skills far beyond his age in mathematics and in writing. For example, he presented ideas in a lucid and comprehensive manner in his writing and displayed analytical skills for advanced algebra. As a result, Ms. Qisha planned to recommend Shaqir for the acceleration program that would allow him to expedite to a higher grade level. However, some of her colleagues suggested that she let Shaqir go through curriculum compacting instead.

- Explain what acceleration program and curriculum compacting are, and whether you agree with Ms. Qisha's plan to recommend Shaqir for the acceleration program instead of curriculum compacting.
- Imagine you are dealing with a gifted student like Shaqir. What are some of the strategies that you could use to maximize their learning outcomes?

MyLab Education **Licensure Exam**

▼ WHAT WOULD THEY DO?

TEACHERS' CASEBOOK Including Every Student

Here is how several expert teachers said they would work with students with a wide range of abilities.

LAUREN ROLLINS • First-Grade Teacher

Boulevard Elementary School, Shaker Heights, OH

Meeting the individual needs of all students is a challenging but essential part of teaching! In this situation, I would create differentiated learning centers, where students could work on curricular components in skill-based groups. The opportunity to work with smaller groups of students whose abilities are similar would allow me to differentiate the curriculum to best meet their academic needs. Groupings would need to be fluid and flexible to ensure that the students were continually being challenged by the curriculum. At each learning center, I would provide a variety of materials and literature related to the subject matter that are designed to meet the wide range of learning styles presented by the students. Additionally, I would allow the students working in the centers to choose which of the provided materials they would like to use to support their learning. Giving the students choices will help with student motivation. I would even consider enlisting their input as to which materials they would like in each center. Finally, I would enlist willing and able parent or community volunteers to assist me in managing the students at the learning centers. The combination of small, skill-based groups, engaging learning materials, and choice will allow students to tackle the curriculum to their fullest potential.

LINDA SPARKS • First-Grade Teacher

John F. Kennedy School, Billerica, MA

Most of our classes are inclusion classes, with limited resources for additional help. At the beginning of the year, I go through all of the records, IEPs, and 504 plans and write down my questions, concerns, and specific information that will help the student. Next, we all meet as a team with the teachers from the previous year and specialists who work with the students. I have found this very helpful in setting up a plan for the students in my class. Then, I don't spend time re-evaluating students in areas where team members already know how students can be most successful. I am given the resources needed to start the year, and we continue to meet throughout the year as additional resources are needed. We are also fortunate to have a volunteer program through the senior center, parent community, and local businesses. These adult volunteers commit to

a specific number of hours a week, are trained by school staff for specific skills the students will need help with, and begin to implement these skills with the students.

PAUL DRAGIN • ESL Teacher, Grades 9–12

Columbus East High School, Columbus OH

This situation has become the norm—at least in public schools in large urban areas. The students with special needs who have been identified should each have an IEP that addresses specifics pertaining to their own cognitive and/or behavioral issues. This would guide my instructional deviation to help ensure that I am providing the curriculum in a format that is more easily comprehended by those who may have challenges that are greater than mainstream students. The medical issue concerning the student with asthma is something that requires a greater sensitivity to ensure that I am alert to any possible medical emergency that may occur in the classroom. Confidence in this trying situation comes from attempting various strategies with the students and discovering, through trial and error, which are most effective at meeting their diverse educational needs.

PAULA COLEMERE • Special Education Teacher—English, History

McClintock High School, Tempe, AZ

It is every teacher's dream to have a room full of eager learners who are all on grade level. In my experience, this never happens! In any classroom, there are students who are below, at, or above grade level in their abilities. First, teachers need to know that fair doesn't mean equal. If I assign a five-paragraph essay to the class, but a student with a learning disability in writing struggles to write that much, I could either extend the due date or modify it to a three-paragraph essay. If the student is really low ability, I may only require a solid paragraph. Likewise, I would challenge the brightest students to go deeper. I would make sure my students knew I believed in them and would build their confidence in their abilities. Proximity is huge in classroom management; by constantly moving around the classroom, I could prompt my students to stay on task or to remind them of appropriate classroom behavior. This would be done very quietly and privately. I would also give a great deal of positive reinforcement while walking around and pointing out all of the things students are doing right. The positive messages must outnumber negative messages.

chapter five

LANGUAGE DEVELOPMENT, LANGUAGE DIVERSITY, AND IMMIGRANT EDUCATION

WHAT WOULD YOU DO?

TEACHERS' CASEBOOK: Cultures Clash in the Classroom

Your high school classes this year are about equally divided among three groups—African Americans, Asians, and Latinos/as. Students from each of the three groups seem to stick together, rarely making friends with students from “outside.”

When you ask students to select partners for projects, the divisions are usually based on shared ethnicity or shared language. At times, insults are exchanged between the groups, and the atmosphere of the class is becoming tense. Often the Asian or Latino students communicate in their first languages—which you don’t understand—and you assume that the joke is on you because of the looks and laughs directed your way. You realize that you are having trouble establishing positive relationships with many of the students whose language, culture, and background are very different from yours, and many other students, picking up on your discomfort, shy away from them too.

CRITICAL THINKING

- What is the real problem here?
- How would you help the students (and yourself) to feel more comfortable?
- What are your first goals in working on this problem?
- How will these issues affect the grade levels you will teach?

Giovanni Cancemi/Shutterstock

OVERVIEW AND OBJECTIVES

Virtually all developed countries, and many developing ones, are becoming more diverse. In many classrooms, multiple languages are spoken. For a range of reasons, including unrest across the globe, families are immigrating to find a better, safer life—and their children will likely be in your classrooms. In this chapter, we look at how the over 6,900 natural languages in the world developed, the role of culture, the stages in language development, and the emergence of literacy. Next we consider diversity in language development and dual language development. But language diversity is more than bilingualism. Because all of us speak at least one dialect, we examine what teachers need to know about dialects and genderlects—a new term for me—along with the role of schools in second- (or third-) language learning. Do the emotions and concerns of these students affect their learning? Finally, we turn to the critical issue for you—how to become a capable and confident teacher of immigrant students and second-language learners. What is the role of bilingual education, English immersion, and sheltered instruction? How can you identify students who are English language learners with special talents or special needs? By the time you have completed this chapter, you should be able to:

- Objective 5.1 Understand how language develops and know how to support emergent literacy.
- Objective 5.2 Discuss what happens when children develop two languages.
- Objective 5.3 Address whether dialect differences affect learning and discuss what teachers can do.
- Objective 5.4 Compare and contrast immigrant, refugee, and Generation 1.5 students, including their learning characteristics and needs.
- Objective 5.5 Discuss teaching methods for English language learners including English immersion, bilingual instruction, and sheltered instruction.
- Objective 5.6 Discuss how teachers can recognize special learning needs and talents when they do not speak their students' first language.

OUTLINE

Teachers' Casebook—Cultures Clash in the Classroom: What Would You Do?

Overview and Objectives

The Development of Language

- What Develops? Language and Cultural Differences
- When and How Does Language Develop?
- Emergent Literacy
- Emergent Literacy and Language Diversity

- Sheltered Instruction

Special Challenges: Students Who Are English Language Learners with Disabilities and Special Gifts

- Students Who Are English Language Learners with Disabilities
- Reaching Every Student: Recognizing Giftedness in Bilingual Students

Summary and Key Terms

Teachers' Casebook—Cultures Clash in the Classroom: What Would They Do?

THE DEVELOPMENT OF LANGUAGE

All children in every culture master the complicated system of their native language, unless severe deprivation or physical problems interfere. This knowledge is remarkable. To have a conversation, children must coordinate sounds, meanings, words and sequences of words, volume, voice tone, inflection, and turn-taking rules, and then link their remarks to what the communication partner just said. Yet, by about age 4, most children have a vocabulary of thousands of words and knowledge of the grammar and rules for basic conversations (Berk & Meyers, 2016; Colledge et al., 2002).

What Develops? Language and Cultural Differences

There are currently more than 6,900 natural languages worldwide, but this number is declining as languages become extinct. For example, in North America before the Europeans and Asians arrived, there were over 300 languages spoken by the native peoples. Now only 8 of these languages remain with at least 10,000 speakers each. This is happening everywhere. About 25% of the languages in the world have fewer than 1,000 speakers remaining (Anderson, 2010).

In general, cultures develop words for the concepts that are important to them. For example, how many different shades of green can you name? Mint, olive, emerald, teal, sea foam, chrome, turquoise, chartreuse, lime, apple . . . and visual artists can add cobalt titanate green, cinnabar green, phthalo yellow green, viridian green, and many others. English-speaking countries have more than 3,000 words for colors. In contrast, the Himba people of Namibia and a tribe of hunter-gatherer people in Papua New Guinea who speak Berinmo have five words for colors, even though they can recognize many color variations. But whether the terms for color are few or many, children gradually acquire the color categories appropriate for their culture (Roberson, Davidoff, Davies, & Shapiro, 2004).

Languages change over time to reflect changing cultural needs and values. The Shoshoni Native Americans have one word that means, “to make a crunching sound walking on the sand.” This word was valuable in the past to communicate about hunting, but today new words describing technical tools have been added to the Shoshoni language, as the group’s life moves away from nomadic hunting. To hear

hundreds of new twenty-first-century tool words, listen to techies talk about computers or video games (W. F. Price & Crapo, 2002).

THE PUZZLE OF LANGUAGE. How can infants around the world master so many different languages? Is there a biological, inborn human capacity for language learning? Newborn babies are remarkably sensitive to sounds; language develops best at certain sensitive periods, as you saw in Chapter 2. Children around the world reach language milestones in different languages at about the same ages. Even deaf children

not exposed to sign language systems have invented their own languages. Research has shown that damage to certain areas of the brain affects language. All these factors indicate that humans may be born with what Noam Chomsky (1957) called a *language acquisition device* and a *universal grammar* or set of rules that applies to all languages (Berk & Meyers, 2016).

Most psychologists today agree that in developing language, humans have built-in biases, rules, grammars, and constraints about language that restrict the number of possibilities considered. For example, young children seem to have a constraint specifying that a new label refers to a whole object, not just a part. Another built-in bias leads children to assume that the label refers to a class of similar objects. So the child learning about rabbits is equipped naturally to assume that “rabbit” refers to the whole animal (not just its ears) and that other similar-looking animals are also rabbits (Jaswal & Markman, 2001; Markman, 1992). But no one has identified all the universal rules. Is there more to language development than inborn rules?

A completely opposing view suggests that humans learn language through imitation, practice, and reward. The child says “cookie” and gets a cookie. This is the process championed by behaviorists such as B. F. Skinner (see Chapter 7). But how does the child invent new combinations and sequences of words that she has never overheard?

BEWARE OF EITHER/OR CHOICES. It likely that many factors—biological, behavioral, cognitive, and cultural—play a role in language development. Humans are set up to learn language, but imitation, experience, practice, and reward play a role as well in helping children learn correct language use. That is why I speak English and not Urdu. Guidance from the environment along with the child’s thinking ability work together to assemble this complicated jigsaw puzzle of language (Waxman & Lidz, 2006).

When and How Does Language Develop?

Table 5.1 shows the milestones of language development, ages 2 to 6, in Western cultures, along with ideas for encouraging development.

SOUNDS AND PRONUNCIATION. By about age 5, most children have mastered the sounds of their native language, but a few sounds may remain unconquered. You saw in Chapter 4 that the sounds of the consonants *l*, *r*, *y*, *s*, *v*, and *z* and the consonant blends *sh*, *ch*, *ng*, *zh*, and *th* are the last to be mastered (Friend, 2014). Young children may understand and be able to use many words but prefer to use the words they can pronounce easily. As children learn to hear differences in the sounds of language, they enjoy rhymes, songs, and general sound silliness. They like stories by Dr. Seuss partly because of the sounds, as evident in the book titles—*All Aboard the Circus McGurkus* or *Wet Pet, Dry Pet, Your Pet, My Pet*. The young son of a friend of mine wanted to name his new baby sister Brontosaurus “just because it’s fun to say.”

VOCABULARY AND MEANING. As you can see in Table 5.1 on the next page, children between ages 2 and 3 can use about 450 words (**expressive vocabulary**) even though they can understand many more (**receptive vocabulary**). By age 6, children’s expressive vocabularies will grow to about 2,600 words, and their receptive vocabularies will be an impressive 20,000-plus words (Otto, 2010). Some researchers estimate that students in the early grades learn up to 20 words a day (P. Bloom, 2002). In the early elementary years, some children may have trouble with abstract words such as *justice* or *economy*. They also may not understand the subjunctive case (“If I were a butterfly”) because they lack the cognitive ability to reason about things that are not true (“But you aren’t a butterfly”). They may interpret all statements literally and thus misunderstand sarcasm or metaphor. For example, fables are understood concretely simply as stories instead of as moral lessons. Many children are in their preadolescent years before they are able to distinguish being kidded from being taunted, or before they know that a sarcastic remark is not meant to be taken literally. But by adolescence, students are able to use their developing cognitive abilities to learn abstract word meanings and to use poetic, figurative language (Owens, 2016).

Expressive vocabulary
All the different words a person uses in speaking or writing.

Receptive vocabulary
The words a person can understand in spoken or written words.

TABLE 5.1 • Milestones in Early Childhood Language and Ways to Encourage Development

AGE RANGE	MILESTONE	STRATEGIES TO ENCOURAGE DEVELOPMENT
Between 2 and 3	Identifies body parts; calls self “me” instead of name; combines nouns and verbs; has a 450-word vocabulary; uses short sentences; matches 3–4 colors; knows <i>big</i> and <i>little</i> ; likes to hear same story repeated; forms some plurals; answers “where” questions	• Help the child listen and follow instructions by playing simple games • Repeat new words over and over • Describe what you are doing, planning, thinking • Have the child deliver simple messages for you • Show the child you understand what he or she says by answering, smiling, and nodding your head • Expand what the child says. Child: “more juice.” You say, “You want more juice?”
Between 3 and 4	Can tell a story; sentence length of 4–5 words; vocabulary about 1,000 words; knows last name, name of street, several nursery rhymes	• Talk about how objects are the same or different • Help the child to tell stories using books and pictures • Encourage play with other children • Talk about places you’ve been or will be going
Between 4 and 5	Sentence length of 4–5 words; uses past tense; vocabulary of about 1,500 words; identifies colors, shapes; asks many questions like “why?” and “who?”	• Help the child sort objects and things (e.g., things to eat, animals) • Let the child help you plan activities • Continue talking about the child’s interests • Let the child tell and make up stories
Between 5 and 6	Sentence length of 5–6 words; average 6-year-old has vocabulary of about 10,000 words; defines objects by their use; knows spatial relations (like “on top” and “far”) and opposites; knows address; understands <i>same</i> and <i>different</i> ; uses all types of sentences	• Praise children when they talk about feelings, thoughts, hopes, fears • Sing songs, rhymes • Talk with them as you would an adult
At Every Age		• Listen and show your pleasure when the child talks to you • Carry on conversations with the child • Ask questions to get the child to think and talk • Read books to the child every day, increasing in length as the child develops

Young children begin to elaborate their simple language by adding plurals; endings for verbs such as *-ed* and *-ing*; small words like *and*, *but*, and *in*; articles (*a*, *the*); and possessives (*the girl’s hair*). A classic study by Jean Berko (1958) demonstrated that children could even apply these rules to make nonsense words into plural, possessive, or past tense forms. For example, when shown a picture of a single “wug,” the preschool children in the study could answer correctly “wugs” when the researcher said, “Now there is another one. There are two of them. There are two _____.” In the process of figuring out the rules governing these aspects of language, children make some very interesting mistakes.

GRAMMAR AND SYNTAX. For a brief time, children may use irregular forms of particular words properly, as if they are saying what they have heard. Then, as they begin to learn rules, they **overregularize** words by applying the rules to everything. Children who once said, “Our car is broken” begin to insist, “Our car is broked.” A child who once talked about her *feet* may discover the *-s* for plurals and refer to her *foots* or *feets*, then learn about *-es* for plurals (*horses*, *kisses*) and describe her *footses*, before she finally returns to talking about her *feet* (Flavell et al., 2002). Parents often wonder why their child seems to be regressing. Actually, these “mistakes” show how logical and rational children can be as they try to assimilate new words into existing schemes. Apparently these overregularizations happen in all languages, including American Sign Language.

Overregularize To apply a rule of syntax or grammar in situations where the rule does not apply, for example, “the bike was broked.”

Early on, children master the basics of **syntax** (word order) in their native language, but overregularizing plays a role in mastering syntax too. For example, because the usual order in English is subject–verb–object, preschoolers just mastering the rules of language have trouble with sentences in any other order. If 4-year-old Justin hears a statement in the passive voice, like “The truck was bumped by the car,” he probably thinks the truck did the bumping to the car because “truck” came first in the sentence. Interestingly, however, in languages where the passive voice is more important, such as the South African language Sesotho, children use this construction much earlier, as young as 3 or 4 (Demuth, 1990). So in talking with young children, in English at least, it is generally better to use direct language. By early elementary school, many children can understand the meaning of passive sentences, but they do not use such constructions in their normal conversations, unless the passive construction is common in their culture.

PRAGMATICS: USING LANGUAGE IN SOCIAL SITUATIONS. Pragmatics involves the appropriate use of language to communicate in social situations—how to enter a conversation, tell a joke, interrupt, keep a conversation going, or adjust your language for the listener. Children show an understanding of pragmatics when they talk in simpler sentences to younger children or command their pets to “Come here!” in louder, deeper voices, or provide more detail when describing an event to a parent who was absent from the event (Flavell et al., 2002). So even young children seem quite able to fit their language to the situation, at least with familiar people.

Rules for the appropriate use of language vary across cultures. For example, years ago Shirley Brice Heath (1989) spent many hours observing White middle-class families and African American families who were poor. She found that the adults asked different kinds of questions and encouraged different kinds of “talk.” White middle-class adults asked test-like questions with right answers, such as “How many cars are there?” or “Which car is bigger?” These questions seemed odd to African American children whose families don’t ask about what they already know. The African American child might wonder, “Why would my aunt ask me how many cars? She can see there are 3.” Instead, African American families encouraged rich storytelling and also teasing that honed their children’s quick wit and assertive responses.

METALINGUISTIC AWARENESS. Around the age of 5, students begin to develop **metalinguistic awareness**. This means their understanding about language and how it works becomes explicit. They have knowledge about language itself. They are ready to study and extend their vocabulary, grammar, and other rules that have been implicit—understood but not consciously expressed. This process continues throughout life, as we all become better able to use language. Learning to read and write, which begins with *emergent literacy*, encourages metalinguistic awareness.

Emergent Literacy

Today, in most languages, reading is a cornerstone of learning, and the foundation for reading is built in early childhood. Early knowledge and skills related to reading often is called **emergent literacy**. Look at Figure 5.1 on the next page, which shows a 6-year-old’s emergent story and grocery list, to see some emerging literacy skills.

What are the most important skills that help literacy emerge? Research has identified two broad categories of skills that are important for later reading (Connor et al., 2014; Douglas & Albro, 2014; Florit & Cain, 2011). *Category 1 skills* involve understanding sounds and codes such as knowing that letters have names, that sounds are associated with letters, and that words are made up of sounds. For example, the ability to name 10 letters is a common preschool/kindergarten benchmark goal in many U.S. states and programs. Is this a good indicator of reading readiness for English? A study that followed 371 children from the end of preschool to the end of first grade found that a better predictor of all reading outcomes was the ability to name 18 uppercase letters and 15 lowercase letters. Letter naming is not the most important skill, but it is easy to assess (Piasta et al., 2012).

Syntax The order of words in phrases or sentences.

Pragmatics The rules for when and how to use language to be an effective communicator in a particular culture.

Metalinguistic awareness Understanding about one’s own use of language.

Emergent literacy The skills and knowledge, usually developed in the preschool years, that are the foundation for the development of reading and writing.

FIGURE 5.1

A STORY AND A GROCERY LIST

This child knows quite a bit about reading and writing—letters make words that communicate meaning, writing goes from left to right and lists go down the page, and stories look different than shopping lists.

Emergent writing samples provided by Kalla Terpenning, who just turned 6.

Source: Woolfolk, A., & Perry, N.E. (2015). *Child and Adolescent Development*. Reprinted and Electronically Reproduced by Permission of Pearson Education, Inc., Upper Saddle River, New Jersey.

Category 2 skills are oral language abilities such as size of expressive and receptive vocabulary, knowledge of syntax, and the ability to understand and tell stories. A study that followed more than 1,000 children from age 3 through third grade concluded, “preschool oral language skills [for example, size of vocabulary, ability to use syntax, ability to understand and tell stories] play an important role along side code skills in predicting reading in the transition to school” (NICHD, 2005b, p. 439). So *beware of either/or choices* between decoding *or* oral language—both are important, but there may be times to emphasize one over the other. Early in the learning-to-read process in English, decoding skills are more important because students need to become fast and automatic in processing letters and words so they have more mental resources available for comprehending what they read. Using all your mental capacity to identify letters and sounds leaves very little space for making meaning. As decoding becomes automatic, the emphasis should change to language comprehension skills (Florit & Cain, 2011).

Inside-out skills The emergent literacy skills of knowledge of graphemes, phonological awareness, syntactic awareness, phoneme-grapheme correspondence, and emergent writing.

Outside-in skills The emergent literacy skills of language, narrative, conventions of print, and emergent reading.

INSIDE-OUT AND OUTSIDE-IN SKILLS. One way to think about emergent literacy that captures both decoding and oral language skills for emergent literacy is the notion of **inside-out skills** and **outside-in skills** (Whitehurst & Christopher Lonigan, 1998), described in Table 5.2.

TABLE 5.2 • Components of Emergent Literacy

COMPONENT	BRIEF DEFINITION	EXAMPLE
Outside-in Processes Knowledge of the information outside the particular printed words being read—that is, knowledge of language, word meanings, concepts, and writing.		
Language	Semantic, syntactic, and conceptual knowledge	A child reads the word “bat” and connects the meaning to knowledge of baseball or flying mammals.
Narrative	Understanding and producing narrative	A child can tell a story, understands that books have stories.
Conventions of print	Knowledge of standard print formats	The child understands that print is read from left-to-right and front-to-back in English; understands the difference between pictures and print or the cover and the inside of the book.
Emergent reading	Pretending to read	Child takes a favorite book and retells the “story,” often by using pictures as cues.
Inside-out Processes Knowledge of letters, sounds, and grammar—the rules for translating the written symbols into spoken words.		
COMPONENT	BRIEF DEFINITION	EXAMPLE
Knowledge of graphemes	Letter-name knowledge	A child can recognize letters and name letters.
Phonological awareness	Detection of rhyme; manipulation of syllables; manipulation of individual phonemes	A child can tell you words that rhyme with “hat.” A child can clap as she says sounds in a word cat: /k/ /ă/ /t/
Syntactic awareness	Repair grammatical errors	A child says, “No! you say I went to the zoo, not I goed to the zoo.”
Phoneme–grapheme correspondence	Letter-sound knowledge	The child can answer the question, “What sounds do these letters make?”
Emergent writing	Phonetic spelling	The child writes “eenuf,” or “hambgr.”
Other Factors	Emergent literacy also depends on other factors such as short-term memory for sounds and sequences, the ability to recognize and name lists of letters, motivation, and interest.	

Source: Woolfolk, A., & Perry, N.E. (2015). *Child and Adolescent Development*. Reprinted and Electronically Reproduced by Permission of Pearson Education, Inc., Upper Saddle River, New Jersey.

For example, when reading a story, to understand even a simple sentence such as, “She ordered an eBook from Amazon?” the reader must know about letters, sounds, grammar, and punctuation. The reader also has to remember the first words as she is reading the last ones. But these inside-out skills are not enough. To understand, the reader needs outside-in skills and knowledge such as: what is an eBook? What does it mean to order? Is this the Amazon River or Amazon online? Why the question mark? Who is asking? How does this sentence fit in the context of the story?

BUILDING A FOUNDATION. What builds this foundation of emergent literacy skills? Especially in the early years, children’s home experiences are central in the development of language and literacy. In homes that promote literacy, parents and other adults value reading as a source of pleasure, and books and other printed materials are everywhere. Parents read to their children, take them to bookstores and libraries, limit the amount of television everyone watches, and encourage literacy-related play such as setting up a pretend school or writing “letters” (Lonigan, Farver, Nakamoto, & Eppe, 2013; Pressley,

MyLab Education
Video Example 5.1

The preschool child in this video has very clear ideas about literacy already. What types of activities would you expect that she and her family engage in regularly?

1996; Sénéchal & LeFevre, 2002). Unfortunately young children growing up in poverty are less likely to get this kind of support. For example, a child in a low-income family is read to about 25 hours *total* during all the preschool years, compared to 1,000 hours for children in higher-income families (Berk & Meyers, 2016).

Childcare workers and teachers can help. In a study that followed almost 300 low-income children from kindergarten to fifth grade, researchers found that the more families were involved with the school, the better their children's literacy development was. School involvement was especially valuable when mothers had less education themselves (Dearing, Kreider, Simpkins, & Weiss, 2006). Five related strategies or activities are critical for younger students:

1. Teaching that helps students “crack the code,” that is, go from spoken sounds to written words and back
2. Joint reading with students, using books as supports for talk about sounds, words, pictures, and concepts
3. Conversations and activities with adults that develop knowledge about language and expand vocabulary and grammar
4. Preschool programs for all children
5. Educating parents to talk with and read to their children, to use words for teaching and learning, not just for controlling their child's behavior (Berk & Meyers, 2016).

For older students, literacy instruction emphasizes reading and writing for understanding. As reading materials become more complex (think fiction, poetry, and many academic subjects) and varied (think Web searches, Wikipedia, visual information as well as traditional texts), reading for understanding becomes more demanding. Students must connect what they read to their existing content knowledge, build vocabulary, draw conclusions, make inferences and predictions, detect patterns and themes, write about what they understand, make claims, provide evidence . . . the list goes on. Research teams around the country continue to test models for developing these complex literacy skills for older students (Connor et al., 2014; Douglas & Albro, 2014; Fogarty et al., 2014).

WHEN THERE ARE PERSISTENT PROBLEMS. Not all children come to first grade with a firm foundation for literacy. Direct teaching of inside-out and outside-in skills in kindergarten and first grade can help many students “crack the code” and move forward. For those who struggle, direct and intensive teaching programs, such as Reading Recovery, can improve reading skills for many students (May et al., 2015). But for some students, reading problems persist into middle and high school (Wanzek et al., 2013). For example, results of the National Assessment of Educational Progress indicated that 1 in 3 fourth-graders and 1 in 4 eighth-graders could not understand what they read in materials at their grade level (Dougals & Alba, 2014).

Intensive early intervention with direct teaching and practice in reading can make a difference, but there is an important additional consideration—*continued support is needed*. Even good interventions lasting many months are not magic bullets that change poor readers into good readers for the rest of their lives. For example, Blachman and her colleagues (2014) followed 58 students who participated in an intensive reading intervention program in second or third grade. The students had individual tutoring 50 minutes a day, 5 days a week, for 8 months. More than a decade later, when these students were 18 to 22 years old, the researchers found only small-to-moderate differences in reading and spelling skills for this group compared to similar students who had not participated in the intensive reading intervention. For students with persistent reading problems, we should think of reading intervention as being more like “insulin therapy, rather than as an inoculation against further reading failure” (Blachman et al., 2014, p. 10). Like people who need insulin on an ongoing basis to be healthy, struggling readers need ongoing teaching and support in reading—you can't “fix it and forget it.”

Emergent Literacy and Language Diversity

Inside-out (letter-sound) and outside-in (language comprehension/meaning) emergent literacy skills are critical for school readiness, regardless of the child's language or languages (Hammer, Farkas, & Maczuga, 2010). But does emergent literacy “emerge” the same way in languages other than English—the language in which much of the research has taken place? There are differences—read on!

LANGUAGES AND EMERGENT LITERACY. English is not an easy language to learn. The same letter can have different pronunciations (How many ways can you pronounce “c”? Think “cook” and “city” for openers). In addition, the same sound can be written different ways, and irregular spellings are plentiful. It makes sense that children would have to become quick and automatic in decoding this complicated system in English before they could devote their mental resources to comprehension. But when languages have more transparent letter-sound systems (e.g., Spanish, German, Italian, and Finnish)—when the letters and the sounds have consistent, predictable connections and few exceptions or irregular spellings—then decoding skills develop more easily, so early schooling can place less emphasis on decoding and focus more on comprehension (Florit & Cain, 2011; Goldenberg, Tolar, Reese, Francis, Bazán, Mejia-Arauz, 2014).

PUT YOURSELF IN THEIR PLACE Imagine you are a young Mexican American child, Josué González (2011). One of your fondest memories is of your grandmother reading to you in Spanish night after night—a wonderful romantic book about the beautiful young Genoveva who lived in a mythical kingdom. It was an exciting tale filled with love, deception, an evil satyr, Genoveva abandoned in the forest to die, and a happy reunion at the end. In school, to learn to read in English, you are given the *Dick and Jane* basal readers, where you read gripping dialogue like, “Look, look Jane. See Spot run. Come Spot come.” By the third grade there is still no plot, and certainly no Genoveva. How excited would you be about reading in English? •

BILINGUAL EMERGENT LITERACY. Most school programs in the United States expect all children to learn to read in English, even if it has to be *Dick and Jane*. According to research by Carol Hammer and her colleagues, this emphasis on reading only in English may not be necessary. In fact, one key factor may facilitate literacy development—growth in receptive language. Recall that *receptive* vocabulary includes the words and language structures you understand, even if you do not use them in your *expressive* vocabulary, the words and structures you actually use when you talk.

In one study, Hammer followed 88 children for 2 years in a Head Start program (Hammer, Lawrence, & Miccio, 2007). The mothers of all the children spoke the Puerto Rican dialect of Spanish. There were two groups of students—those who had been expected to speak both English and Spanish from birth and those who were not expected to learn English until they began Head Start at age 3. Hammer and colleagues concluded “growth in children’s English receptive language abilities during Head Start, as opposed to the level of English they had achieved by the end of Head Start, positively predicted the children’s emergent reading abilities in English and the children’s ability to identify letters and words in English” (p. 243). And it did not matter if the students spoke English and Spanish from birth or if they just started speaking English in school. In addition, growth in Spanish language abilities predicted reading performance in Spanish as well as English. The same results held for high school students learning German when their first language was Russian or Turkish. Better listening comprehension in the first language predicted better reading comprehension in the second language of German—even for Turkish students whose first language is very different from German (Edele & Stanat, 2016).

GUIDELINES

Supporting Language and Promoting Literacy

FOR TEACHERS

Use stories as a springboard for conversations.

Examples

1. Retell stories you have read with your students.
2. Talk about the words, activities, and objects in the books. Do the students have anything like these in their home or classroom?

Identify and build on strengths the families already have (Delpit, 2003).

Examples

1. What are the histories, stories, and skills of family members? Students can draw or write about these.
2. Show respect for the student's language by celebrating poems or songs from the language.

Provide home activities to be shared with family members.

Examples

1. Encourage family members to work with children to read and follow simple recipes, play language games, keep diaries or journals for the family, and visit the library. Get feedback from families or students about the activities.
2. Give families feedback sheets, and ask them to help evaluate the child's schoolwork.
3. Provide lists of good children's literature available locally—work with libraries, clubs, and churches to identify sources.

FOR SCHOOL COUNSELORS AND ADMINISTRATORS

Communicate with families about the goals and activities of your program.

Examples

1. Have someone from the school district, the community, or even an older student translate into the language of the child's family any material you plan to send home.

2. At the beginning of school, send home a description of the goals to be achieved in your class—make sure it is in a clear and readable format.
3. As you start each unit, send home a newsletter describing what students will be studying—give suggestions for home activities that support the learning.

Involve families in decisions about curriculum.

Examples

1. Have planning workshops at times family members can attend—provide childcare for younger siblings, but let children and families work together on projects.
2. Invite parents to come to class to read to students, take dictation of stories, tell stories, record or bind books, and demonstrate skills.

Make it easier for families to come to school.

Examples

1. Provide babysitting for younger children while families meet with teachers.
2. Consider the transportation needs of families—can they get to school?

One implication is that teachers and parents should focus on continuing language development and not worry about rushing children into speaking English exclusively. As Hammer and her colleagues note, “If bilingual children’s language growth is progressing well in either Spanish or English during the preschool years, positive early English and Spanish reading outcomes result in kindergarten” (2007, p. 244). These findings are consistent with the recommendations of the Society for Research in Child Development (SRCD): “Investing in dual-language instead of English-only programs and encouraging pre-kindergarten attendance can improve learning opportunities for Hispanic children and increase their chances of success” (SRCD, 2009, p. 1). The *Guidelines: Supporting Language and Promoting Literacy* give some ideas.

DIVERSITY IN LANGUAGE DEVELOPMENT

Many children learn two or more languages simultaneously while they are growing up. What does this involve?

Dual-Language Development

If they are exposed to two languages from birth, **bilingual** children (children who speak two languages) reach the language milestones in both languages on the same schedule as **monolingual** children (children learning only one language). Initially, bilingual children may have a larger vocabulary in the language that they are learning from the person with whom they spend the most time or have the closest bond, so a child who stays home all day with a Chinese-speaking parent will likely use more Chinese words. But over time, these children can become fully and equally bilingual if the dual-language exposure (1) begins early in life (before age 5); (2) occurs across a wide and rich range of contexts; and (3) is systematic, consistent, and sustained in the home and community (Petitto, 2009; Rojas & Iglesias, 2013). Another requirement is that the second language must provide more than 25% of the child's language input; with less exposure, the child is unlikely to learn the second language (Pearson, Fernandez, Lewedeg, & Oller, 1997; Topping, Dekhinet, & Zeedyk, 2011). Bilingual children may mix vocabularies of the two languages when they speak, but this is not necessarily a sign that they are confused, because their bilingual parents often intentionally mix vocabularies as well, selecting the word that best expresses their intent (Creese, 2009). So, with consistent and sustained engagement in two languages, children can be fully bilingual.

Research on the brain and bilingualism shows that people who learn two languages before about age 5 process both languages in the same way as those who learn only one language and use the same parts of their brains, usually in the left hemisphere (Klein, Mok, Chen, & Watkins, 2014). In contrast, people who learn a second language later have to use both hemispheres of their brain as well as the frontal lobe and working memory. They have to apply more cognitive effort. As Laura-Ann Petitto (2009) notes, "*Later* bilingual exposure does *change* the typical pattern of the brain's neural organization for language processing, but early bilingual exposure does not" (p. 191).

SECOND-LANGUAGE LEARNING. What if you didn't learn two languages as you were growing up? When and how should you learn a second language? To answer that question, you have to remember the distinction between **critical periods** for learning (if learning doesn't happen then, it never will) and **sensitive periods**, times when we are especially responsive to learning. There is no critical period that limits the possibility of language learning by adults (Marinova-Todd, Marshall, & Snow, 2000). In fact, older children go through the stages of language learning faster than young children. Adults have more learning strategies and greater knowledge of language in general to bring to bear in mastering a second language (Diaz-Rico, 2014). But research on the brain and bilingualism suggests "*there is most definitely a 'sensitive period' for optimal bilingual language and reading exposure and mastery*. Age of first bilingual exposure predicts how strong a reader a bilingual child can and will become in each of their two languages" (Petitto, 2009, p. 192).

Even though there is no *critical* period for learning a language, there appears to be a critical period for learning accurate language pronunciation. The earlier people learn a second language, the more their pronunciation is near native. Researchers have found that from birth to about 4 months, infants can discriminate all the basic sound building blocks from any of the world's 6,900 or so languages. But after about 14 months they lose this capability and hone in on the sounds of the language they are learning. For children learning two languages at once, however, this developmental window seems to stay open longer, so these children can continue to differentiate sounds past 14 months (Petitto, 2009).

After adolescence it is almost impossible to learn a new language without speaking with an accent. Even if a child overhears a language, without actually learning it

Connect and Extend to PRAXIS II®

Bilingual Issues (IV, B4)

Identify the major issues related to the debate over bilingual education. Explain the major approaches to bilingual education, and describe steps that a teacher can take to promote the learning and language acquisition of non-English-speaking students.

Bilingual Speaking two languages and dealing appropriately with the two different cultures.

Monolingual Speaking only one language.

Critical periods If learning doesn't happen during these periods, it never will.

Sensitive periods Times when a person is especially ready to learn certain things or responsive to certain experiences.

formally, this can improve later learning. “Although waiting until adulthood to learn a language almost guarantees a bad accent, having overheard the target language during childhood seems to lessen this predicament substantially” (T. K. Au, Knightly, Jun, & Oh, 2002, p. 242). So the best time to acquire two languages on your own through exposure (and to learn native pronunciation for both languages) is early childhood (Berger, 2018).

BENEFITS OF BILINGUALISM. There is no cognitive penalty for children who add a second or third language. In fact, there are benefits. Higher degrees of bilingualism are correlated with increased cognitive abilities in such areas as concept formation, creativity, theory of mind, cognitive flexibility, attention and executive functioning, and understanding that printed words are symbols for language (Bialystok, Craik, & Luk, 2012; Kempert, Saalbach, & Hardy, 2011). In addition, bilingual children have more advanced *metalinguistic* understanding of how language works; for example, they are more likely to notice grammar errors. Even more impressive, children from monolingual English-speaking families who attended bilingual schools and learned Spanish had better phoneme awareness and reading comprehension than their peers who were educated in an English-only program.

Looking at all this research, Petitto (2009) concluded that “early bilingualism offers no disadvantages; on the contrary, young bilinguals may be afforded a linguistic and a reading advantage. . . . Moreover, learning to read in two languages may afford an advantage to children from monolingual homes in key phoneme awareness skills vital to reading success” (p. 193). In addition, speaking two languages is an asset when graduates enter the business world. Some researchers believe that speaking two languages may even provide some protection against Alzheimer’s dementia in old age (Berger, 2015). Maybe humans evolved to speak multiple languages because this would have survival value, so perhaps the “contemporary pockets of civilization where one language is spoken are the aberrant deviation; in other words, perhaps our brains were neurologically set to be multilingual” (Petitto & Kovelman, 2003, p. 14).

LANGUAGE LOSS. If you mastered your own first language, then added a second or third language, you are an example of *additive bilingualism*—you kept your first language as you added another. But if you experience discrimination against your first language, you may leave that language behind as proficiency is gained in a new language—an example of *subtractive bilingualism* (Hamers & Blanc, 2000; Montrul, 2010; Norbert, 2005). Immigrants are more likely to experience discrimination and therefore “subtract” their first language. But if family members and the community value and use a children’s first language, they are more likely to keep that language when a second one is learned.

Even though the advantages of bilingualism described earlier seem clear, many children and adults are examples of subtractive bilingualism—they are losing their heritage language (Montrul, 2010). **Heritage language** is the language spoken in a student’s home or by older relatives while the larger society outside the home speaks a different language (English in the United States). Often students who lose their heritage language were born in a new country after their parents or grandparents immigrated, so the students never lived in the country where everyone spoke their heritage language. Two Chinese American college students interviewed by K. F. Wong and Xiao (2010) expressed concerns this way:

One of my biggest fears is that later on having kids and them not being able to speak Chinese, because my level of Chinese is not at the same level of my parents, and so I’m scared that it will get lost. (p. 161)

My heritage language is definitely Toishan (Taishan), but even so, my parents don’t always speak it fluently, so . . . I know somewhere down the line, I’m probably the last one to even speak it . . . and I feel like it is not my heritage anymore. (p. 165)

Heritage language The language spoken in the student’s home or by members of the family.

Balanced bilingualism Adding a second language capability without losing your heritage language.

Rather than losing one language to gain another, the goal should be **balanced bilingualism**—equal fluency in both languages (V. Gonzalez, 1999). The first language may be the only way a child can communicate with parents, grandparents, and other

family members. This language is the main channel for transmitting family values, histories, and traditions, so it is the basis for identity and self-esteem (Peregoy & Boyle, 2017). But outside their homes, English connects these students to academic, social, and economic opportunities, so both languages are invaluable (Borrero & Yeh, 2010).

In many countries there are special schools that focus on instruction in heritage languages and cultures. Students attend these schools in the afternoon, on the weekend, or during the summer in addition to their regular public school. In Great Britain, these institutions are called *supplementary* or *complementary* schools. In Australia they are called *community language* or *ethnic schools*. In the United States and Canada, the name often is *heritage language schools* (Creese, 2009). Here are some ideas for learning about heritage schools in your area, suggested by Angela Creese (2009), a professor of educational linguistics at the University of Birmingham, United Kingdom:

- Find out which complementary/heritage schools are located in your area, and make contact with them.
- Attend the awards ceremonies and presentations of your students who attend complementary/heritage schools. Show your commitment to their bilingual and multicultural projects.
- Find out if teachers work in both the complementary/heritage and mainstream school sectors. Ask them to undertake professional development workshops for other teachers in school.
- Ask a lead teacher of a complementary/heritage school to give an assembly.
- Encourage small-scale research and/or practical projects to harness the potential links between complementary and mainstream schooling (p. 272).

Signed Languages

People who can communicate in both a spoken and a signed language or in two different signed languages are considered bilingual (Petitto, 2009). There are a number of other parallels between spoken languages and the many signed languages used around the world, such as American Sign Language (ASL), Signed English (United States, Ireland, New Zealand, Australia, Great Britain), Lingua de Signos Nicaraguense (Nicaraguan Sign Language), Warlpiri Sign Language (Australia Aboriginal), and Langue des Signes Québécoise (LSQ), or Quebec Sign Language. Each of these languages is distinct and not simply a derived version of a spoken language. For example, people using Quebec Sign Language and French Sign Language cannot understand each other, even though the French spoken language is common to both countries.

Both spoken and signed languages have large vocabularies and complex grammars. Laura-Ann Petitto and Ioulia Kovelman (2003) suggest that the same mechanisms for language acquisition are used for both spoken and signed languages. In addition, the milestones for signed language are the same as for spoken language. For example, children “say” their first words at about the same time, around 12 months, with both spoken and signed languages (P. Bloom, 2002). In fact, research with children learning a signed and a spoken language from infancy demonstrates that “being exposed to two languages from birth—and, in particular, being exposed to a signed and a spoken language from birth—does not cause a child to be language delayed or confused” (Petitto & Kovelman, 2003, p. 16). As with two spoken languages, children can become balanced bilinguals in a spoken and a signed language.

What Is Involved in Being Bilingual?

An estimated 52.6 million people in the United States can speak Spanish today, giving the country the second-largest Spanish-speaking population in the world, behind only Mexico. Of the states, New Mexico has the most Spanish speakers with 47%, followed by Texas and California with 38% each, and Arizona with 30%. By 2050, the estimates are that the United States will have the largest number of Spanish speakers of any country in the world—about 138 million (Burgen, 2015; Perez, 2015). Since 1990, the number of Asian immigrants in the United States has more than doubled, from almost 5 million in

TABLE 5.3 • Myths and Misconceptions About Being Bilingual

In this table, L1 means the original language and L2 means the second language.

MYTH	TRUTH
Learning a second language (L2) takes little time and effort and “children just pick it up” when they are exposed to the language.	Learning English as a second language takes 2–3 years for oral proficiency and 6–9 years for academic language use. To learn L2, students need to have a reason to communicate, access to English speakers, interaction, support, feedback, and time.
All language skills (listening, speaking, reading, writing) transfer from L1 to L2.	Reading is the skill that transfers most readily.
Code switching is an indication of a language disorder.	Code switching indicates high-level language skills in both L1 and L2.
All bilinguals easily maintain both languages. Children do not lose their first language.	It takes great effort and attention to maintain high-level skills in both languages. Loss of L1 and underdevelopment of L2 (semilingual in L1 and L2) are problems for second language learners.
Learning two languages in early childhood will confuse or delay a child’s acquisition of English.	Most young children throughout the world successfully learn more than one language from their earliest years. In fact, learning two languages benefits brain development.
To learn English successfully, students’ parents need to speak only English at home.	Children need to use both languages in many contexts.
Reading in L1 is detrimental to learning English.	Literacy-rich environments in either L1 or L2 support development of necessary prereading skills.
Language disorders must be identified by tests in English.	Children must be tested in both L1 and L2 to determine language disorders.

1990 to almost 13 million in 2014 (Zong & Batalova, 2016). With these increased numbers come many misconceptions about bilingualism, as you can see in Table 5.3.

What does it really mean to be bilingual? Some definitions of *bilingualism* focus exclusively on a language-based meaning: People who are bilingual speak two languages. But being bilingual also means mastering the knowledge necessary to communicate in two cultures, dealing with potential discrimination, while still maintaining a sense of your own identity, so bilingualism requires biculturalism as well (Borrero & Yeh, 2010; S. J. Lee, Wong, & Alvarez, 2008). Being a successful bilingual *student* has one more requirement—learning *academic language*.

Contextualized and Academic Language

Proficiency in a second language has two separate aspects: face-to-face *basic communication/conversation skills* and *academic language* (E. E. Garcia, 2002; Herrell & Jordan, 2016). *Basic communication and conversation skills* include, for example, using appropriate vocabulary and sentences, asking and answering questions, starting and stopping conversations, listening, and understanding and using idioms.

Academic language spans the entire range of language used in elementary and secondary schools and universities, and includes having fluency in reading and writing; understanding grammar and syntax; knowing specialized vocabulary; following written

Academic language The entire range of language used in elementary, secondary, and university-level schools including words, concepts, strategies, and processes from academic subjects.

TABLE 5.4 • Common Errors and Accomplishments as Students Learn a Second Language

LANGUAGE STAGE	COMMON ERRORS AND LIMITATIONS	ACCOMPLISHMENTS
During the first year of learning the language	• No speech at all • Only understands one word at a time • Mispronounces words • Leaves out words • One- or two-word responses • Relies heavily on context	• Uses pantomiming, gestures, pointing to communicate • Can use “yes,” “no,” or single words
During the second year of learning the language	• Basic pronunciation and grammar mistakes • Limited vocabulary	• Uses whole sentences • Good comprehension (in context) • Uses language to function well socially
During the third year and beyond of learning the language	• Some errors with complex grammar	• Can tell whole stories • Good comprehension • Beginning to understand and use academic language • Larger vocabulary

Source: Based on Miranda, T. Z. (2008). *Bilingual Education for All Students: Still Standing after All These Years*. In L. S. Verplaetse & N. Migliacci (Eds.), *Inclusive Pedagogy for English Language Learners: A Handbook of Research-Informed Practices* (pp. 257–275). New York, NY: Erlbaum.

and oral directions; collaborating with other students on assignments; understanding different types of texts and forms of writing such as fiction, poetry, math problems, science charts and graphs, and timelines in history; mastering study skills such as outlining, summarizing, and reading comprehension; and understanding abstract, higher-order, complex concepts. Academic language includes the general words and concepts used in many subjects such as *analyze*, *evaluate*, or *summarize*, as well as words and strategies specific to disciplines such as *factor the equation* or *derivative* in math, a *factor* in the latest election results, or a *derivative* in finance (you see how complicated this gets when the same word has two very different meanings in different fields). In fact, academic language should be considered a *new language* that people must learn in order to succeed in school. So all students, but especially those who may not speak formal English at home, must become bilingual and bicultural academically; they must learn the new ways of speaking and cultural rules required for school (Echevarría, Vogt, & Short, 2017; Vogt, Echevarría, & Short, 2010).

It takes about 2 to 3 years in a good-quality program for children who are learning a new language to be able to use *basic* language face-to-face in conversations. The stages for basic second-language learning are shown in Table 5.4.

Mastering *academic* language skills such as reading texts in the new language takes much longer than 3 years; it is more like 6 to 9 years, depending on how much academic knowledge the student already had in his or her native language. So children who seem to “know” a second language in conversation may still have great difficulty with complex schoolwork in that language (Bialystok, 2001; Verplaetse & Migliacci, 2008). Here is how one tenth-grader from Mexico described how her teacher helped her master academic language:

What I really love about my ESL teacher is that she explains how to organize our thoughts and how to write in school ways. She also teaches us what to do to be good, critical readers. That is so helpful in my other classes and I know it will be good for life. (Walqui, 2008, p. 111)

Cultural differences might interfere with developing academic English and content understanding in many ways. For example, many Asian students come from a culture

GUIDELINES

Promoting Language Learning

Provide structures, frameworks, scaffolds, and strategies.

Examples

1. "Think aloud" as you solve a problem by building on and clarifying the input of students.
2. Use visual organizers, story maps, or other aids to help students organize and relate information.

Support verbal explanations with visual cues.

Examples

1. Use facial expressions and gestures to emphasize meaning.
2. Use charts, maps, graphs, pictures, films, videos, Web pages, and concrete materials.

Teach relevant background knowledge and key vocabulary concepts.

Examples

1. Informally assess students' current background knowledge. Directly teach needed information, if missing.
2. Focus on key vocabulary words, and use those words consistently.

Give focused and useful feedback.

Examples

1. Focus feedback on meaning, not grammar, syntax, or pronunciation.
2. Give frequent, brief, clear feedback. Use words from the student's first language when you can.
3. Make sure to let students know when they are successful.
4. Break assignments and activities into smaller, "bite-sized pieces" with feedback after each "bite."

Keep students involved and engaged.

Examples

1. Use small group and pairs work.
2. Create situations where students talk at length.
3. Challenge students with clear higher-order questions. Allow them time to think and write out answers, maybe in pairs.

Show authentic respect for students' culture and language.

Examples

1. Learn about your students' personal and language background: What languages are spoken at home? When did the family arrive? How long have they lived in the United States? What schooling did they receive in other countries?
2. Learn about the students' religious background, food preferences and restrictions, and family customs; then incorporate students' experiences into writing and language arts activities.
3. Learn some key words in the students' languages—this is an opportunity for you to become a more global and sophisticated language learner.
4. View diversity as an asset; reject cultural deficit notions.

Sources: Based on Peregoy, S. F., & Boyle, O. F. (2017). *Reading, Writing, and Learning in ESL: A Resource Book for Teaching K–12 English Learners* (7th ed.). Boston, MA: Pearson; Echevarría, J., Vogt, M., & Short, D. J. (2017). *Making Content Comprehensible for Secondary English Learners: The SIOP® Model* (5th ed.). Boston: Pearson; and Gersten, R. (1996b). Literacy Instruction for Language-Minority Students: The Transition Years. *The Elementary School Journal*, 96, 217–220.

that believes asking the teacher questions is rude and inappropriate because questioning implies that the teacher has done a poor job of instruction. In Asian classrooms this might cause the teacher to lose face in front of the students—an entirely unacceptable situation. Thus, teachers need to ask themselves why their English learners are not asking questions. And class discussion may be considered a waste of time in cultures in which the teacher is viewed as the source of authoritative knowledge. How could students possibly learn anything from other students who are not authorities? So beliefs about learning shaped by culture and previous experiences in different kinds of classrooms may explain why English learners seem quiet and reluctant to speak in class. English language learners also may think that their teachers are not very good because they do not explain everything. They may strongly prefer memorization as a learning strategy if memorization was emphasized in their previous schools (thanks to Dr. Alan Hirvela at Ohio State University for pointing out these possible cultural differences in beliefs about schools and teachers).

The *Guidelines: Promoting Language Learning* give ideas for promoting language learning, but you should also keep cultural differences in mind as you teach.

DIALECT DIFFERENCES IN THE CLASSROOM

Communication is at the heart of teaching, but as we have seen in this chapter, culture affects communication. In this section, we examine two kinds of language differences—dialect differences and genderlects.

Dialects

STOP & THINK When you want a soft drink, what do you call it? Do you think people in other parts of the United States use the same term? •

Growing up in Texas, we always asked, “Do you want a *coke*?” If the answer was yes, the next question was, “What kind—Coca-Cola, root beer, 7-Up, orange?” When I moved to New Jersey, I had to ask for a *soda*. If I asked for a coke, then that is just what I got. Twenty years later, at our moving-to-Ohio party, my colleague who had grown up in Columbus, Ohio, said, “You are going to have to learn to speak Midwestern and ask for a ‘*bottlapop*.’” Different regions have different ways of speaking—both in their accents and word usage. For example, in New England, many people refer to a traffic circle as a “rotary,” and ice cream sprinkles are “jimmies.” An Italian sandwich may be a submarine, torpedo, hero, wedge, hoagie, muffaletta, or po’boy, depending on where you try to order it. In the United States, there are at least 10 regional or geographic dialects, and no child born in this country learns dialect-free English (Owens, 2016)

A **dialect** is a language rule system used by a particular group. The dialect is part of the group’s collective identity. Every person reading this book speaks at least one dialect, maybe more, because there is no one absolute standard English. The English language has several dialects; for example, Australian, Canadian, British, and American. Within each of these dialects are variations. A few examples of dialects of American English are Southern, Bostonian, Cajun, Asian English, and African American English. Are the minimalist codes of texting (“BTW, u r sum1 I like”) a new dialect (Owens, 2016)?

Dialects differ in their rules about pronunciation, grammar, and vocabulary, but it is important to remember that these differences are not errors. Each dialect is logical, complex, and rule governed. An example of this is the use of the double negative (Brice & Brice, 2009). In many versions of American English, the double-negative construction, such as “I don’t have no more,” is incorrect. But in many dialects such as some varieties of African American English and in other languages (e.g., Russian, French, Spanish, and Hungarian), the double negative is part of the grammatical rules. To say “I don’t want anything” in Spanish, you must literally say, “I don’t want nothing,” or, “No quiero nada.” My husband, from Pennsylvania, drops “to be” in some sentences such as, “The lawn needs mowed” and “The car needs washed.”

DIALECTS AND PRONUNCIATION. Dialects also differ in pronunciation, which can lead to spelling problems. In some varieties of African American English and in Southern dialects, for instance, less attention is paid to pronouncing the ends of words. A lack of attention to final consonants, such as *s*, can lead to failure to indicate possession, third-person singular verbs, and plurals in the standard way. So *John’s book* might be *John book*, and the singular and plural will sound the same for words such as *thinks*, *wasps*, and *lists*. When endings are not pronounced, there are more *homonyms* (words that sound alike but have different meanings) in the student’s speech than the unknowing teacher may expect; *spent* and *spend* might sound alike, for example. Even without the confusions caused by dialect differences, English has many homonyms. Usually, teachers give special attention to words such as these when they come up in spelling lessons. If teachers are aware of the special homonyms in student dialects, they can teach these differences directly.

DIALECTS AND TEACHING. How can teachers cope with linguistic diversity in the classroom? First, they can be sensitive to their own possible negative stereotypes about

MyLab Education
Video Example 5.2

In this video, Dr. Walt Wolfram differentiates between dialect and accent, and he reminds teachers of the need to be sensitive to the social functions of dialectal differences and code switching.

Dialect Any variety of a language spoken by a particular group.

children who speak a different dialect. Second, teachers can ensure comprehension by repeating instructions using different words and by asking students to paraphrase instructions or give examples. The best teaching approach seems to be first to focus on understanding the students and accepting their language as a valid and correct system, but then to teach the alternative forms of English (or whatever the dominant language is in your country) that are used in more formal work settings and writing so that the students will have access to a range of opportunities. Jean Anyon (2012) described how she accomplished this naturally in her elementary classes:

Indeed, I thought the language my students used was inventive and lovely. I had my students write poems and stories in their own language. We would appreciate the music of their voices. Then, we would talk about the differences between what they wrote and the way I spoke, as I was from a different culture—the white middle class. We would do some translations of their talk and mine, back and forth. In this way, language patterns were seen as different, not good or bad. Discussion of the need for them to learn standard English to function in a white world came naturally out of our activities, not as an imposition. (p. 2)

Moving between two speech forms is called **code switching**—something we all have learned to do. Sometimes, the code is formal speech for educational or professional communication. At other times, the code is informal for talk among friends and family. And occasionally, the codes are different dialects. Even young children recognize variations in codes. Delpit (1995) describes the reaction of one of her first-grade students to her very first reading lesson. After she carefully recited the memorized introduction from the teacher’s manual, a student raised his hand and asked, “Teacher, how come you talkin’ like a white person? You talkin’ just like my momma talk when she get on the phone.”

Learning the alternative versions of a language is easy for most children, as long as they have good models, clear instruction, and opportunities for authentic practice.

Genderlects

If you had to guess what **genderlects** are, based on what you know about dialects, you probably would figure out that genderlects are different ways of talking for males and females. Boys and girls have some small differences in their speech. Girls tend to be slightly more talkative and affiliative in their speech (affiliative speech is talk intended to establish and maintain relationships). But much of the research has been conducted with White, middle-class children, and the results do not necessarily hold for other groups and cultures. For example, some research reports that girls are more likely to cooperate and to talk about caring, whereas boys are more competitive and talk about rights and justice. But other studies have found that African American girls in one study were just as likely as boys to compete and talk about their rights in conversations (Leaper & Smith, 2004).

As with most aspects of language, cultural differences occur in genderlects. Interrupting is a good example. In the United States, boys interrupt more often than girls, but in Africa, the Caribbean, South America, and Eastern Europe, females interrupt males much more often than they do in the United States. And in Thailand, Hawaii, Japan, and Antigua, the style of speaking for boys and girls is overlapping; this overlapping talk is not interruption but cooperative turn taking (Owens, 2016).

Genderlects Different ways of talking for males and females.

TEACHING IMMIGRANT STUDENTS

Felipe Vargas is a fifth-grader who came with his family from Mexico to the United States more than 3 years ago so his father could take a job in a chicken-processing plant. Many Mexicans have come to work at the plant, and now there is a Spanish-speaking church, a Mexican grocery, and a Mexican bar and restaurant in the little northern Georgia town

where they live. Felipe's mother, who takes care of the home and children, speaks no English, but his father and his older brother, Enrique, both speak a little. Enrique was 15 when the family came to this country. He left school after 1 year in a program for English for speakers of other languages (ESOL) and went to work in the chicken plant. He is proud to be contributing to the family but dreams of being a car mechanic; he spends all his free time fixing cars for neighbors and earns a little extra money that way. Felipe's oldest sister is 15 now, and, like him, spent 2 years in an ESOL program before transitioning to regular English-speaking classes. Her parents have chosen a husband for her from "back home," and she plans to leave school as soon as she turns 16, although she would rather not marry the man her parents have chosen. His two younger sisters are 8 and 4; the youngest is in a special Head Start class to learn English, and the other is repeating second grade because she is having a hard time learning to read.

Felipe gets mostly Cs in school. He still struggles a bit with reading his textbooks, but he has many Anglo friends in his class and has no trouble talking English with them; in fact, he translates for his parents when they come to school for parent conferences, which they do whenever his father can get off work. Math is his real talent; he consistently gets As on his tests, and he is in the highest "math group," so he goes to another teacher for math. That teacher calls him "Phillip" and tells him he could be an accountant or maybe an engineer when he grows up. Felipe likes this idea, but his father says that college would cost too much money and reminds him that the family plans to go back to Mexico someday, when they have saved enough to buy a small farm, which is his father's dream.

There are so many students like Felipe and his siblings in American schools today. For the remainder of this chapter, we explore ways of teaching these students so that their dreams of college and careers can come true wherever they finally live.

Immigrants and Refugees

Immigrants are people who voluntarily leave their country to become permanent residents in a new place. In the United States, children living in immigrant families make up about 25% of children and adolescents under the age of 18 and one-fifth of all kindergarten students (Koury & Votruba-Drzal, 2014; Turner, 2015). People from Mexico, like Felipe's family, are the largest U.S. immigrant group, followed by people from other Latin American countries, and then from East and South Asia (Zeigler & Camarota, 2015). **Refugees** are a special group of immigrants who also relocate voluntarily, but they are fleeing their home country because it is not safe. The United States requires that individuals seeking refugee status demonstrate "that they were persecuted or fear persecution due to race, religion, nationality, political opinion, or membership in a particular social group" (U.S. Citizenship and Immigration Services, 2017). Since 1975, more than 3,000,000 refugees have permanently resettled in the United States, half of them children. In 2016, about 85,000 refugees were admitted to the United States, mostly from Asia, the Middle East, and Africa (Igielnik & Krogstad, 2017).

In earlier decades, these new immigrants were expected to assimilate—to enter the cultural **melting pot** and become like those who had arrived earlier. For years, the goal of American schools was to be the fire under the melting pot. Immigrant children who spoke different languages and had diverse religious and cultural heritages were expected to come to the schools, master English, and learn to become mainstream Americans. Of course, most schools were designed to serve European American middle-class children, so it was the immigrant children who were expected to do the adapting and changing—rather than the schools. *Involuntary immigrants*, descendants of the slaves forced to migrate to the United States, often were not welcome at all in the cultural melting pot.

In the 1960s and 1970s, some educators suggested that immigrants, students of color, and poor students had problems in school because they were "culturally disadvantaged" or "culturally handicapped." The assumption of this **cultural deficit model** was that the students' home culture was inferior because it had not prepared them to fit into the schools. Today, educational psychologists reject the idea of cultural deficits. They believe

Immigrants People who voluntarily leave their country to become permanent residents in a new place.

Refugees A special group of immigrants who also relocate voluntarily, but who are fleeing their home country because it is not safe.

Melting pot A metaphor for the absorption and assimilation of immigrants into the mainstream of society so that ethnic differences vanish.

Cultural deficit model A model that explains the school achievement problems of ethnic minority students by assuming that their culture is inadequate and does not prepare them to succeed in school.

MyLab Education Podcast 5.1

In this podcast, textbook author Anita Woolfolk talks about how important it is for teachers to understand and accept cultural differences in their students. Listen to find out how cultural awareness can prevent conflicts between students, teachers, and parents.

MyLab Education Video Example 5.3

In this video, directors and teachers of ELL programs and bilingual education discuss population changes taking place in their schools. They serve increasing numbers of students and see dramatic influx in diversity of nationalities and native languages. Imagine the classrooms in these schools as you listen to these educators discuss the changes.

English language learners (ELLs) Students who are learning English and whose primary or heritage language is not English.

that incompatibilities may exist between the student's home culture and the expectations of the U.S. school (Gallimore & Goldenberg, 2001). Also, there is an increasing sense among many ethnic groups that they do not want to assimilate completely into mainstream American society. Rather, they want to maintain their culture and identity while still being a respected part of the larger society. Multiculturalism is the goal—more like a salad bowl filled with many ingredients instead of the prior melting pot idea (J. A. Banks, 2015; Stinson, 2006).

In past decades, most U.S. immigrants were concentrated in large urban areas and in California, Texas, Arizona, and New York. But today there are immigrants in many other cities and towns, particularly in the Midwestern states. Given the challenges of teaching students who have a range of English speaking abilities coupled with the demands of accountability testing, it is clear that teachers everywhere are under pressure (S. B. Garcia & Tyler, 2010). And there is not much help; less than 1% of elementary and secondary school teachers are prepared to teach English as a second language (Aud et al., 2010).

Classrooms Today

English language learners (people who are learning English, often called ELLs) are the fastest growing segment of the U.S. population. Some researchers project that by 2030, about 40% of the students in pre-kindergarten through high school will speak limited English (Guglielmi, 2012). By some estimates, Latinos alone will comprise about one quarter of the U.S. population by 2065 (Cohn, 2015). And U.S.-born children of immigrant families make up another group needing specialized language teaching. Even at the beginning of high school, these students may still lack the skills in academic English—school language—needed to succeed in their often complex, abstract courses (Dixon et al., 2012; Slama, 2012).

These changes are not limited to the United States. By 2031, it is projected that one in three Canadians will belong to a visible minority and one in four will be foreign born, so it is likely that the number of people who speak languages other than the official English and French will increase in Canada as well (Catalyst, 2016). In fact, all the developed countries have many immigrant students. For example, in the Netherlands, more than half of the students under age 12 in the Amsterdam schools are from immigrant families, and in Australia, one in four people were born overseas (Crul & Holdaway, 2009; Martin, Liem, Mok, & Xu, 2012). These numbers are only increasing with the recent refugee crises in the world.

FOUR STUDENT PROFILES. Following are four general profiles of students who are ELLs in today's classrooms (Echevarría & Graves, 2015).

- **Balanced bilinguals.** These students speak, read, and write well both in their first language and in English. They have the academic knowledge needed to continue learning in both languages and the skills and attitudes to do so. These students may not present difficult teaching challenges, but they do need to *maintain* their skills in both languages and cultures.
- **Monolingual/literate students.** These students are literate in their native language (at or above grade level when working in their native language), but speak limited English. The teaching challenge here is to help the students develop English and continue to learn academic subjects.
- **Monolingual/preliterate students.** These students are not literate. They may not read or write in their native language or they may have very limited literacy skills. Some have never attended school. In addition, they speak limited English. These students require the greatest support in learning both academic subjects and language.
- **Limited bilingual.** These students can converse well in both languages, but for some reason they have trouble learning academically. They may have underlying challenges such as learning disabilities or emotional problems. Further testing often is helpful to diagnose problems.

These student profiles are related to the distinction we encountered earlier in the chapter between basic conversational language and academic language. You may remember that it takes from 2 to 3 years to develop good conversational language, but 6 to 9 (or even as many as 10) years to master academic language. Be aware, however, that in many academic areas some children from immigrant families will surpass their classmates from native-born families, so don't assume there will be problems—get to know the student (Koury & Votruba-Drzal, 2014). If you teach at a school with many students who are ELLs, school personnel will probably do formal assessments to provide appropriate placements for these students.

Generation 1.5: Students in Two Worlds

PUT YOURSELF IN THEIR PLACE Imagine you are this person:

You came to the United States at about the age of 1. Your family was undocumented. You have a younger brother and sister who were born in the United States and are legal citizens, but you are not. Your parents and older siblings worked hard, often two jobs, so that the younger children could get a good education. You attended kindergarten, elementary, and high school in your family's new community in the United States. You graduated from high school with good grades and hoped to attend college, but soon discovered you did not qualify for scholarship support and would have to pay international student tuition, which you cannot afford. Even as a hardworking and promising student, you cannot legally work, vote, or drive in many states, in spite of the fact that you have lived virtually all your life in the United States and speak fluent English. •

If you were this student, you would be a member of a large group, often called **Generation 1.5** because their characteristics, educational experiences, and language fluencies are somewhere in between those of students born in the United States and students who are recent immigrants (A. L. Gonzalez, 2010). They were not born in the United States, but have lived here most of their lives because they came with their families when they were very young. The language spoken in their homes may not be English, but they often speak fluent conversational English, even if their academic English is not as well developed. Dubarry and Alves de Lima (2003) describe other several kinds of Generation 1.5 students:

- Students from U.S. territories such as Puerto Rico, sometimes called “in-migrants.”
- U.S.-born children of immigrants who live in close-knit communities where the heritage language is maintained by the residents for family and business life.
- Children who are sent by their often-wealthy parents to live with older siblings in order to receive education in the United States, sometimes called “parachute children.”
- Children of families who move back and forth between different countries.
- Immigrants who speak other “Englishes” such as English from Jamaica, East India, or Singapore.

These students may share several characteristics and challenges. They may not have developed strong literacy skills in the language used at home because their schooling was not in that language. They may have acquired much of their English through listening to and speaking with friends or older siblings, watching television, or listening to music. They have been called “ear learners” because they have built their knowledge of English on the language they have heard in their environment. But what they hear is often colloquial language or slang, so they may have trouble learning how to read and write accurately in English. Many of us know if the grammar is correct in what we hear or read because we have heard (mostly) accurate grammar all our lives—our ears have taught us well. But for many Generation 1.5 students, their ear learning has given them an imperfect, even inaccurate conception of English grammar. Because they are “ear learners,” they may use incorrect verb or noun forms, mispronounce plurals, or mix up

Generation 1.5 Students whose characteristics, educational experiences, and language fluencies are somewhere in between those of students born in the United States and students who are recent immigrants.

words that sound very similar; for example, *confident* and *confidence*. They rely on context, gestures, facial cues, and intonations to make sense of language, so reading is more difficult and proofreading is hard because they cannot “hear” mistakes. Complex academic reading and writing assignments are very challenging (Harklau, Losey, & Siegal, 1999; Reid & Byrd, 1998; Roberge, 2002).

In contrast, many of my international graduate students who learned English mostly as “eye learners” through reading, writing, and vocabulary and grammar exercises can write well, but they have more difficulty with oral interactions. Knowing what kind of students you have and how they first learned English should help you understand the mistakes they make and the challenges they face.

Affective and Emotional/Social Considerations

PUT YOURSELF IN THEIR PLACE You walk into one of your education classes. The instructor moves to the lectern and says:

Mina-san, ohayō gozaimasu. Kyō wa, kyō iku shinrigaku no jū gyō ja arimasen. Kyō wa, nihon no bangō, ichi kara jū made benkyō oshimasu. Soshite, kono kyō shitsu wa Amerika no kyō shitsu ja arimasen. Ima wa Nihon no kyō shitsu desu. Nihon no kyō shitsu dewa, shinakerebanaranai koto wa mittsu mo arimasu. Tatsu, rei, suwaru. Mina-san, tatte kudasai. Doshite tatteimasen ka? Wakarimasen ka?

The class continues in the same way until you are handed the “test” and told to “Do your best—this is 20% of your grade.” You can’t believe it! What would you do? •

Does this seem impossible? Actually, one of my doctoral students (Yough, 2010) designed this lesson (without the test) so his educational psychology class would experience how it feels to have important content taught in a language you don’t speak (assuming your Japanese is a bit rusty!). Research on ELL students shows that they may experience severe challenges and stress in school. They may feel that they don’t belong and that others are making fun of them or just ignoring them. Everyone else seems to know the rules and the right words. It takes courage and persistence to keep trying to communicate; it is easier to say as little as possible. So the practice in communicating that these students desperately need just doesn’t happen. Also, research shows that anxiety is more likely to affect attention and comprehension in reading when students read in a second language compared to students reading in their first language, especially for language learners who are prone to reading anxiety (Rai, Loschky, & Harris, 2015).

What can teachers do to support students’ courage and persistence in communicating? The first step is to create a classroom community that is caring and respectful. We explore strategies for creating classroom community in Chapter 13. Echevarría and Graves (2015) suggest additional steps to provide emotional support and increase self-esteem for ELL students, as you can see in the *Guidelines: Providing Emotional Support and Increasing Self-Esteem for Students Who Are ELLs*.

Another problem is related to cultural differences. As we saw earlier, students who immigrate to the United States in their middle or high school years may have experienced very different educational systems and educational values “back home.” They may have been very successful in those systems, perhaps excelling by memorizing the content required by the curriculum. When they encounter a different approach to education, suddenly they may struggle and feel as if they know little or nothing. As a teacher, you need to learn the strengths of these students and acknowledge their abilities—and build on their knowledge. We turn to that topic next.

Working with Families: Using the Tools of the Culture

As noted earlier in the chapter, when families are more involved in the schools, their children are more successful (Dearing et al., 2006). Here we consider several ways to engage families: building on funds of knowledge, Welcome Centers, and student-led conferences.

GUIDELINES

Providing Emotional Support and Increasing Self-Esteem for Students Who Are ELLs

Create learning activities that promote success in all kinds of reading and writing.

Examples

1. Have weekly individual conferences with younger students and record their retelling of a story. Let students edit and revise the dictation and read it to a partner.
2. Do interactive journals with older students—collect them each week and write back.
3. Include many kinds of writing, not just academic styles of writing. For older students this could mean Tweets, Facebook posts, plays, blogs, letters to the editor, or email communications with friends. For younger students you might use family stories, greeting cards, thank you notes, shopping lists—think everyday practical writing.

Make sure students have plenty of time to practice and get careful, targeted corrections.

Examples

1. Point out privately what is correct, almost correct, and wrong in written work.
2. Be sensitive about public oral corrections, and build on what is correct, but do not accept clearly incorrect answers.

Connect teaching to relevant knowledge from students' lives.

Examples

1. Ask students to survey family members about favorite films. Use film characters to discuss elements of literature—plot, point of view, and so on.
2. Have students create construction firms and plan projects to learn math concepts.

Actively involve learners.

Examples

1. Use timelines in history compared to personal timelines based on family history.
2. Do projects in science based on animals or farming for rural students.

Use different grouping strategies.

Examples

1. Try pairs for writing stories and practicing oral presentations.
2. Create small teams to research recent immigrant groups' culture and language.

Provide native language support.

Examples

1. Learn and use as much of the students' language as possible—if they can learn, so can you.
2. Find Internet translation sources and local native-speaking volunteers.
3. Bring native-language magazines and books into the classroom.

Involve family and community members.

Examples

1. Bring in storytellers, local business owners, artists, and craftspeople.
2. Create a Welcome Center for your class.

Hold high expectations for all students, and communicate these expectations clearly.

Examples

1. Keep scrapbooks about previous students who have gone on to careers or college.
2. Don't accept mediocre work.
3. Be a model of respect for diversity and an enemy of bigotry.

Based on Echevarría, J., Vogt, M., & Short, D. J. (2017). *Making Content Comprehensible for Secondary English Learners: The SIOP® Model* (5th ed.). Boston: Pearson and Echevarría, J., & Graves, A., *Sheltered Content Instruction: Teaching English Language Learners with Diverse Abilities* (5th ed.). © 2015. Boston: Pearson.

FUNDS OF KNOWLEDGE AND WELCOME CENTERS. Luis Moll and his colleagues wanted a better way to teach the children of working-class Mexican American families in the barrio schools of Tucson, Arizona (Moll et al., 1992). Rather than adopt a model of remediating the students' deficits, Moll decided to identify and build on the tools and cultural **funds of knowledge** of their families. By interviewing the families, the researchers identified their extensive knowledge about agriculture, ranching, caring for animals, economics and budgeting, construction, building codes, accounting, sales, loans, labor laws, child care, medicine, household management, appliance repair, mechanics, science, and religion. When teachers based their assignments on these funds of knowledge, students were more engaged and teachers were educated about their students' lives. For example, by participating in a *funds of knowledge project*, one teacher realized that she always had thought about her students in terms of deficits and problems—poor achievement,

Funds of knowledge
Knowledge that families and community members have acquired in many areas of work, home, and religious life that can become the basis for teaching.

alienation, family troubles, and poverty. But then she got to know the families by focusing on their resources, not their limitations. She also learned that her students' actions often were misinterpreted, as she documented in her journal. One example journal entry:

Wednesday (11/25/92) The music teacher commented (to me), "You know, Leticia has missed two chorus rehearsals." Before I could answer, the school drama teacher stepped in to add, "Oh, she's very irresponsible." She had signed up to be in the Drama Club and had only been to two meetings. I said "Wait a minute. . . ." I then told her how Leticia's younger brother was being hospitalized for a series of operations, and when the mother had to leave, she left Leticia in charge of caring for her two younger siblings. In fact, her missing after-school rehearsals was an act of responsibility, obedience and loyalty to her family. (Gonzales et al., 1993)

By engaging with students' families, this teacher learned about the valuable cognitive resources in the community, and her respect for her students and their families increased.

Moll's work also was the basis for the *Welcome Center* project in a pre-kindergarten through fifth-grade elementary school in the Southwest. Within 4 years the school had gone from 12% to 43% Latino/a, with most of these students recently arrived immigrants. The Welcome Center was an inviting place where recent immigrant families could meet each other and learn by sharing expertise (DaSilva Iddings, 2009). The center was a bright, comfortable, informal space with a small kitchen, picnic tables, computer and printer, books and magazines in Spanish and English, math manipulatives, showcases for children's work, and other welcoming features. Fifth-graders offered homework assistance after school at the center. Spanish-speaking families taught classes in Spanish, cooking, and dancing for community members. English literacy activities were provided for adults and children learning together. The center produced many success stories—teachers who connected with students' families and came to appreciate the value of their students' language and culture, immigrant families who moved toward citizenship, and others who opened businesses and restaurants. Connections with families may be especially important for the success of immigrant students. The *Guidelines: Family and Community Partnerships* have more ideas.

MyLab Education Video Example 5.4

In this brief video, Dr. Olmedo describes funds of knowledge that emphasize the importance of tapping into the cultural funds of knowledge children bring to the classroom.

STUDENT-LED CONFERENCES. Parent–teacher conferences have been around for as long as I can remember. These can be productive but also disappointing or confrontational too. One way to get students more invested in the conferences and maybe even in learning itself is to put the students in charge of leading the conference, presenting work to their parents, and explaining what they have learned and how they learned it. Students take more responsibility for why they succeeded, and perhaps why they failed. How could they improve? What are their goals for the next marking period? When students lead conferences, parents may be more likely to attend and more engaged. With careful planning and preparation, teachers can create a sense of a team working for the good of the student (Haley & Austin, 2014).

There are many ways to use and design student-led conferences. Most teachers work with students to set clear learning goals for specific projects and perhaps provide rubrics to guide self-assessment (see Chapter 15 for more idea rubrics). It is important to notify families well in advance and perhaps even gather information from them about their hopes and concerns for their child, their interests, and their funds of knowledge. Let them know that their child will be leading the conference and, if necessary, will be translating for them. Also assure families that there will be time at the end of the conference for them to meet with you privately, without their child, to share concerns and ask questions.

During the conference, the student leads the discussion, showing work and perhaps responding to prompts such as, "What I like about this paper is. . . ." "I learned. . . ." "If I did this again, I would improve. . . ." "My next goal is. . . ." To do a good job of leading the conference and explaining their work, students should practice with each other. With all this preparation, it is discouraging if family members do not show up, so you should have a back-up plan for another adult to sit in and engage with the student. See Table 5.5 for a timeline planning guide.

GUIDELINES

FAMILY AND COMMUNITY PARTNERSHIPS

Welcoming All Families

Show respect (Vaughn, Boss, & Schumm, 2014).*Examples*

1. Learn the correct pronunciation of each student's first name and family name.
2. Make sure each student's heritage is represented in the curriculum somewhere.
3. Treat the students' families with the kind of respect you expect as a parent.

Make sure communication with families is understandable.*Examples*

1. Use the families' home languages wherever possible in all communications from you and your class.
2. Use oral forms of communication—phone calls or home visits—whenever possible.

Balance positive and negative messages.*Examples*

1. Send home notes or descriptions about a child's accomplishments or acts of kindness.
2. Explain disciplinary actions as ways of helping children succeed.

Establish systems for welcoming new families.*Examples*

1. Assign more experienced "buddy" parents to communicate with new families.
2. Connect with multilingual media in your community to make announcements about school.

Make sure messages get through.*Examples*

1. Establish telephone trees or texting networks.
2. Set the expectation that you will send a weekly note home so parents can ask their children about it.
3. Establish a class newsletter or Web site, and incorporate multiple languages.

TABLE 5.5 • Timeline for Planning and Conducting Student-Led Conferences

WHEN	WHAT
At the beginning of the grading period	Identify several pieces of student work: projects, essays, drawings, quizzes, reports, and so on, that will be the focus of the student-led conference at the end of the grading period. Establish clear assessment criteria and perhaps a rubric for each.
During the grading period	Have students practice self-assessment using the criteria or rubrics and share their assessments with others in the class.
A few weeks before the conferences	Send a notice to families explaining the student-led conferences and asking for information such as the child's interests, responsibilities at home, likes and dislikes about school, time spent watching TV or gaming, number and age of siblings, or hours spent on homework. You might also ask about family favorite activities, parents' interests and funds of knowledge, and their concerns and goals for their child.
A week before the conferences	Have students make final notes about how they will present their work to their families, and then role-play conferences with each other, taking the role of both parents and students.
In the week after the conference	Ask students to reflect on what they learned while preparing for and leading the conference. How will they use the experience to guide their future learning?

TEACHING IMMIGRANT STUDENTS WHO ARE ENGLISH LANGUAGE LEARNERS

In the United States, students who are just learning English are sometimes described as being **limited English proficient (LEP)**. More often, as we have seen, these *students* are called English Language Learners (ELLs), because their primary or heritage language is not English. **English as a second language (ESL)** is the name given to the *classes* devoted to teaching these students English. Many people prefer term *ESOL* (English for Speakers of Other Languages) because students learning English may be adding it as a third or fourth language. This was the name for Felipe Vargas's program (you met him earlier). Having limited proficiency in English often means lower academic achievement and poorer job prospects. So one issue around diversity in language development is how we should teach these students.

Two Approaches to English Language Learning

Virtually everyone agrees that all citizens should learn the official language of their country. But when and how should instruction in that language begin? Is it better to teach students who are ELLs to read first in their native language, or should they begin reading instruction in English? Do these children need some oral lessons in English before reading instruction can be effective? Should other subjects, such as mathematics and social studies, be taught in the primary (home) language until the children are fluent in English? As you can see in the *Point/Counterpoint*, debates about this question have raged for quite a while.

RESEARCH ON BILINGUAL EDUCATION. There are strong advantages for simultaneous bilingual maintenance learning. Remember Petitto's (2009) finding that monolingual English speakers who participated in a bilingual program excelled in the skills needed for reading in both languages. When the National Literacy Panel on Language—Minority Children and Youth reviewed studies of English-only *immersion* versus native language *maintenance* programs, they found that the students in the native language maintenance programs performed better on many different measured outcomes (Francis, Lesaux, & August, 2006). A summary of the research comparing immersion with language maintenance programs in Europe reached the same conclusion—bilingual maintenance programs are more effective (Reljic, Ferring, & Martin, 2015).

But do programs always “do what they say”—that is, does the actual teaching match the name given the program? Maybe not. In a study that directly compared immersion and maintenance programs in 128 classrooms in Texas and California, Lee Branum-Martin and his colleagues (Branum-Martin, Foorman, Francis, & Mehta, 2010) found that the amount of teaching conducted in English and Spanish could not be predicted by type of program—there were many local variations. Some English immersion teachers used quite a bit of Spanish, and some Spanish language maintenance programs taught quite a bit in English. Another finding was that Spanish language maintenance programs had a positive impact on English performance.

A study funded by the U.S. Department of Education (Gersten et al., 2007) identified five major recommendations for English learners, summarized here (Peregoy & Boyle, 2017).

1. Begin instruction with a formative assessment (see Chapter 15) of reading to determine exactly what the English learners know and what they are ready to learn, and to identify students who will need more help in reading.
2. Use small-group interventions to focus instruction on the areas of need identified in the assessments.
3. Target teaching essential vocabulary for the content in your curriculum as well as common words, phrases, and expressions used in class.

Limited English proficient (LEP) A term also used for students who are learning English when their primary or heritage language is not English—not the preferred term (English language learner; ELL) because of the negative connotations.

English as a second language (ESL) The classes devoted to teaching English to students who are English language learners.

Structured English immersion (SEI) An environment that teaches English rapidly by maximizing instruction in English and using English at a level appropriate to the abilities of the students in the class who are English language learners.

Semilingual A lack of proficiency in any language; speaking one or more languages inadequately.

POINT/COUNTERPOINT: What Is the Best Way to Teach Students Who Are ELLs?

There are two basic positions on this question: one that focuses on *immersion* in English-only teaching to make the transition to English as quickly as possible. The other approach attempts to *maintain or improve* the native language and use that language as the primary teaching language until English skills are more fully developed.

POINT ▶ Structured English immersion is the best approach for ELL students. Proponents of the *immersion/fast transition* approach believe that English ought to be introduced as early and as intensively as possible; they argue that valuable learning time is lost if students are taught in their native language. Early advocates cited the successes of the Canadian Immersion program as evidence that language immersion works (Baker, 1998). In an article for educational administrators, Kevin Clark claims, “These programs have the potential to accelerate ELLs’ English language development and linguistic preparation for grade-level academic content” (K. Clark, 2009, p. 42). Many schools today follow this line of thinking and offer **Structured English immersion (SEI)**. Perspectives on SEI differ, but usually it is defined as having two basic features: (1) teachers use English as much as possible in instruction, and (2) the level of the students’ abilities in the class determines how teachers use and teach English—the instruction must be appropriate for all students’ abilities (Ramirez, Yuen, & Ramey, 1991). There are at least three reasons why schools adopt this approach (K. Clark, 2009):

1. Some states have mandated this immersion by law and have limited the amount of teaching that can be done in the child’s native language.
2. The accountability tests that all school districts in the United States must administer are in English. Schools where students don’t score well on these tests face penalties, so getting the test takers to achieve English proficiency as fast as possible benefits the schools.
3. Schools are concerned that ELL students who do not get intensive and continuing English instruction may learn adequate conversational English but never develop the academic English needed for achievement in secondary schools and beyond.

Immersion in a language is a good way to learn a new language and is the basis for many language-learning programs around the world (K. Clark, 2009).

COUNTERPOINT ▶ Students’ native language should be maintained. Teaching in English and hoping students will figure it out is not the same as *teaching* English. Early proponents of *native-language maintenance instruction* raise four important issues (Gersten, 1996b; Goldenberg, 1996; Hakuta & Garcia, 1989). Today these programs often are called *dual-language instruction*.

1. Deep learning in the first language supports second-language learning. For example, research on a large national sample that followed eighth-graders for 12 years found that for Latino students, proficiency in the first language of Spanish predicted reading ability in English and English reading ability predicted achievement in school and in careers (Guglielmi, 2008, 2012). The metacognitive strategies and knowledge

developed when students learn to read in their first language are transferred to reading in a second language as well (van Gelderen, Schoonen, Stoel, de Glopper, & Hulstijn, 2007). So maintaining and increasing proficiency in the first language is important. The learning strategies and academic content (math, science, history, etc.) that students learn in their native language are not forgotten when they learn English. In addition, vocabulary learned in one language can support vocabulary learning in another language (Goodrich, Lonigan, & Farver, 2013).

2. Children who are forced to try to learn math or science in an unfamiliar language are bound to have trouble. What if you had been forced to learn fractions or biology in a second language that you had studied for only a semester? Some psychologists believe students taught by this approach may become **semilingual**; that is, they are not proficient in either language. Being semilingual may be one reason the dropout rate is so high for Latino students from low socioeconomic status backgrounds (Ovando & Collier, 1998).
3. If the first language is neglected and the entire emphasis is on English, students may get the message that their home languages (and therefore, their families and cultures) are second class.
4. Years ago, Kenji Hakuta cited a “paradoxical attitude of admiration and pride for school-attained bilingualism on the one hand and scorn and shame for home-brewed immigrant bilingualism on the other” (Hakuta, 1986, p. 229). Ironically, by the time students have mastered academic English and let their home language deteriorate, they reach secondary school and are encouraged to learn a “second” language. Sometimes native speakers of Spanish are encouraged to learn French or German, so they risk becoming semilingual in three languages (Miranda, 2008).

Beware of Either/Or. It is difficult to separate politics from practice in the debate about bilingual education. It is clear that high-quality bilingual education programs can have positive results. Students improve in the subjects that were taught in their native language, in their mastery of English, and in self-esteem as well (Crawford, 1997; Francis, Lesaux, & August, 2006; Reljic, Ferring, & Martin, 2015). ESL programs seem to have positive effects on reading comprehension (Proctor, August, Carlo, & Snow, 2006). But attention today is shifting from debate about general approaches to a focus on effective teaching strategies. As you will see many times in this book, a combination of clarity of learning goals and direct instruction in needed skills seems to be effective and includes learning strategies and tactics, teacher- or peer-guided practice leading to independent practice, authentic and engaging tasks, opportunities for interaction and conversation that are academically focused, and warm encouragement from the teacher (Cheung & Slavin, 2012; Gersten, 1996b; Goldenberg, 1996).

FIGURE 5.2

A VISUAL TO SUPPORT LEARNING HOW TO WRITE AN ESSAY

The teacher explains that one good structure for an essay is like a train, with each part playing an important role. For example, the introduction tells where the essay is going just like the engine determines the direction of the train.

Source: Peregoy & Suzanne F.; Boyle. *Reading, Writing and Learning in ESL: A Resource Book for Teaching K–12 English Learners* (7th ed.). © 2017, p. 414 (Figure 10.5). Reprinted and electronically reproduced permission of Pearson Education, Inc., Upper Saddle River, NJ.

4. Directly teach academic English—develop the students' abilities to read texts, write academic assignments, and use formal language and argument.
5. Make wide use of peer-assisted learning, particularly work in pairs, to complete academic tasks.

There are many effective strategies for teaching English language learners. Next we will look at two examples: visual strategies and reader response.

VISUAL STRATEGIES. Visual strategies provide supports for learning everything from letter-sound connections, to vocabulary, to understanding text structure. Young students can draw pictures and label them in two languages. They can learn about higher-level concepts by grouping pictures in categories and labeling the categories. Older students might learn about writing an essay by referring to the visual support in Figure 5.2 (Peregoy & Boyle, 2017).

LITERATURE RESPONSE GROUPS. The goal of teaching ELLs is for them to become capable readers, writers, and speakers of English. *Literature response groups*, also called *literature circles*, provide these opportunities using fiction and nonfiction texts. Three to six students read a text, then discuss and debate what they read, making sure everyone participates, speaks, listens, and understands. They might also write

FIGURE 5.3

AN EXAMPLE LITERATURE RESPONSE SHEET

Teachers using this sheet remind students to accept and respect the opinions of others, remember that there are many different interpretations of a story, and feel free to develop their own questions.

1. If you did (or didn't) like the book, was there one event, character, or aspect of the book that caused this reaction? What? Why?
2. Do your response group members share a common reaction to the book? What reactions are the same? What are different?
3. If you were faced with the same problems as the main character in the book, would you have responded in a similar manner? Why?
4. How was the main character feeling when we first met him or her? Have you ever felt like the character?
5. How do you feel about the ways the main character behaves with other characters?
6. Did any of the characters remind you of anyone you have known? Yourself?
7. Do you think the author was trying to teach us something? If so, what?
8. Would you change the ending of the book? If so, how?
9. Which character would you like to have met? What would you want to say or do when you met the character?
10. Did your feelings change toward the character(s) as the story progressed? What made your feelings change?
11. If you could step inside the book and be part of the story, where would you enter? Who would you be? What would you do? How would these things change the story?
12. What things would be different in this story if it took place in a different period of time or a different place?

Source: Peregoy & Suzanne F.; Boyle. *Reading, Writing and Learning in ESL: A Resource Book for Teaching K–12 English Learners* (7th ed.). © 2017, p. 349 (Figure 9.2). Reprinted and electronically reproduced by permission of Pearson Education, Inc., Upper Saddle River, NJ.

about the reading and then critique each other's work. Often the teacher provides a discussion guide such as the one shown in Figure 5.3 from Peregoy and Boyle, (2017, p. 349).

BILINGUALISM FOR ALL: TWO-WAY IMMERSION. Students in the United States need to master both conversational and academic English to achieve at high levels, but they should not sacrifice their native language in the process. The goal of schools should be *balanced bilingualism*. One approach to reaching this goal is to create two-way immersion classes that include native speakers of one language and native speakers of the other, with instruction in both languages. The objective is for both groups to become fluent in both languages (Peregoy & Boyle, 2017; Sheets, 2005). My daughter spent a summer in such a program in Quebec and was ahead in every French class after that.

For truly effective education for students who are ELLs, we will need many bilingual teachers. If you have a competence in another language, you might want to develop it fully for your teaching. Thirty-two states and the District of Columbia report shortages of bilingual teachers (Liebtag & Haugen, 2015) and promoting language learning is a responsibility for most teachers. Figure 5.4 on the next page shows some teaching strategies that will support language and literacy development across the grade levels.

When students exit an immersion or a bilingual program with some English skills, they are not finished learning. The next phase for many students is sheltered instruction.

Sheltered Instruction

The challenge for most teachers working with immigrant and ELL students is to teach the subject matter and develop students' English language skills at the same time. **Sheltered instruction** is one approach that has proved successful in reaching both goals. Sheltered

MyLab Education
Video Example 5.5

The challenge for most teachers working with immigrant and ELL students is to teach the subject matter and develop students' English language skills at the same time. Sheltered instruction is one approach that has proved successful in reaching both goals. In this video, Dr. Vogt explains why sheltered instruction is important for immigrant and ELL students.

Sheltered instruction

Approach to teaching that improves English language skills while teaching content to students who are English language learners by putting the words and concepts of the content into context to make the content more understandable.

FIGURE 5.4

TEACHING STRATEGIES FOR PROMOTING LEARNING AND LANGUAGE ACQUISITION

Effective teaching for students in bilingual and ESL classrooms combines many strategies—direct instruction, mediation, coaching, feedback, modeling, encouragement, challenge, and authentic activities—many opportunities to read, write, and talk.

Sheltered Instruction Observation Protocol (SIOP®) An observational system to check that each element of sheltered instruction is present for a teacher.

instruction teaches content to ELL students by putting the words and concepts of the content into context to make the content more understandable. Strategies include simplifying and controlling language, giving attention to the relevant grammar and forms of English—helping students “crack the code,” using visuals and gestures, and including real-life supports and examples. In addition, there is an emphasis on student talk and discussion instead of the teacher doing all the talking. To be clearer about what good sheltered instruction looks like, Jana Echevarría and her colleagues (Echevarría, Vogt, & Short, 2017) identified eight key elements: preparation, building background, comprehensible input, strategies, interaction, practice and application, lesson delivery, and review and assessment. Then the researchers developed an observational system to check that each element was included in their lesson plans. The system is called the **Sheltered Instruction Observation Protocol (SIOP®)**. Figure 5.5 gives some examples of what each element of the SIOP® might include.

What might a SIOP® lesson look like? There are many ways to design lessons that meet the standards in Figure 5.5. Table 5.6 on page 237 describes seven different lesson structures and activities to help students understand content and develop language skills.

FIGURE 5.5

SOME EXAMPLES OF THE SHELTERED INSTRUCTION OBSERVATION PROTOCOL (SIOP®)

The SIOP® has 30 characteristics or areas to assess during observation. Each characteristic is rated from 4 (Highly Evident) to 0 (Not Evident) or NA (Not Applicable). These ratings are converted into a score. (L1 means the original language, and L2 means the second language.)

Observer: _____

Date: _____

Grade: _____

Class: _____

Total Points Possible: 120 (Subtract 4 points for each NA given)

Total Points Earned _____

Teacher: _____

School: _____

ESL level: _____

Lesson: Multi-day Single-day (circle one)

Percentage Score _____

Directions: Circle the number that best reflects what you observe in a sheltered lesson. You may give a score from 0–4.

Cite under "Comments" specific examples of the behaviors observed.

MyLab Education Self-Check 5.5

SPECIAL CHALLENGES: STUDENTS WHO ARE ENGLISH LANGUAGE LEARNERS WITH DISABILITIES AND SPECIAL GIFTS

If you remember the four profiles of ELLs described earlier, you know that one type of student may have learning disabilities, but it is very difficult to tell because the student's language is limited. ELLs with disabilities are difficult to diagnose—expert assessment is necessary (S. B. Garcia & Tyler, 2010). Sometimes students are inappropriately placed in special education just because they have problems with English, but other times, students who would benefit from special services are denied placement because their problems are assumed to be simply language learning issues (U.S. Department of Education, 2004). In addition, students with special talents and gifts may be difficult to recognize.

TABLE 5.6 • Ideas for Lesson Structures in SIOP® That Encourage Understanding of Content and Build Language Skills

STRUCTURE	EXAMPLE/WHAT DOES IT LOOK LIKE?	RATIONALE/WHY DOES IT WORK?
Think-Pair-Share	Instead of asking questions of the whole class and calling on two or three students to respond, the teacher asks everyone to think of an answer or respond to a prompt and tell it to a partner. Then, the teacher calls on some students to share their responses with the whole class.	Gives all students a chance to think and speak about the topic. Allows teachers to monitor student understanding of the content and language objectives during a lesson.
Chunk and Chew	The teacher pauses after every 10 minutes and directs students to talk with a partner or in a small group about what they have just learned. In SIOP® lessons, the student talk is carefully structured by the teacher with specific prompts and/or sentence starters, such as “If I could interview any author we read this year, it would be. . . . because. . . .”	Makes new information easier to learn by “chunking” it into learnable, bite-size pieces (see Chapter 8 for why this is important). Gives students a chance to talk using concepts and content from the lesson.
Roam and Review	The teacher poses a reflection question (e.g., “What was the most important thing you learned today?” or “What surprised you in our studies today?”) and students think silently, then stand and roam the classroom, discussing their ideas with classmates.	Gives students a chance to synthesize what they have learned and communicate it in a more conversational manner. They practice communicating.
Podcasts	Students prepare a 2- to 3-minute oral summary on a topic they have selected or the teacher has assigned. They rehearse and then record it on a podcast or an audio file for use on the class computer.	Provides practice in speaking and the chance to hear and improve language. Having an audience increases motivation and encourages careful preparation.
TV Talk Show	Small groups plan a talk show on a topic with multiple parameters that they have studied. One student is the host and interviewer; others are the guests. For example, after studying extreme weather phenomena, one guest might be an expert on hurricanes, another on blizzards, a third on earthquakes, and a fourth on tornadoes.	Video recording of the show allows the teacher or the students to assess how well the students spoke, used key vocabulary, responded to host questions, and so forth. Having an audience increases motivation and encourages careful preparation.
Writing Headlines	Students capture the essence of a day’s lesson, section of a text read, video watched, or information presented orally by writing a headline, and then share their headline.	Encourages students to use descriptive language and focus on word choice to create compelling headlines.
E-Journals and Wiki Entries	Students write in an e-journal daily or once a week to reflect on what they have been learning. At the end of a unit, the teacher might ask students to write an online entry for a class wiki that presents key information on a topic being studied.	Encourages synthesizing information and writing longer pieces.

Students Who Are English Language Learners with Disabilities

As a teacher, one of your decisions will be whether to refer a struggling ELL student for testing. Of course, the first step is to use the best teaching approaches, incorporating sheltered instruction to develop both subject matter learning and English language development. But if progress seems much slower than usual, you might ask the following questions, suggested by George De George (2008): What is the student’s educational background, and what is the background of his or her family? When did the student come to the United States? Being born in the United States but speaking another language at home or immigrating when very young can make learning in the early grades more difficult. Students who immigrate after successfully learning in their home country schools have literacy skills to build on. They know some academic content, and they

TABLE 5.7 • Identifying Bilingual Students with Gifts and Talents

Here are some ideas for identifying bilingual students with gifts and talents. Watch for students who:

_____ Learn English quickly
_____ Take risks in trying to communicate in English
_____ Practice English skills by themselves
_____ Initiate conversations with native English speakers
_____ Do not frustrate easily
_____ Are curious about new words or phrases and practice them
_____ Question word meanings; for example, "How can a bat be an animal and also something you use to hit a ball?"
_____ Look for similarities between words in their native language and English
_____ Are able to modify their language for less-capable English speakers
_____ Use English to demonstrate leadership skills; for example, use English to resolve disagreements and to facilitate cooperative learning groups
_____ Prefer to work independently or with students whose level of English proficiency is higher than theirs
_____ Are able to express abstract verbal concepts with a limited English vocabulary
_____ Are able to use English in a creative way; for example, can make puns, poems, jokes, or original stories in English
_____ Become easily bored with routine tasks or drill work
_____ Have a great deal of curiosity
_____ Are persistent; stick to a task
_____ Are independent and self-sufficient
_____ Have a long attention span
_____ Become absorbed with self-selected problems, topics, and issues
_____ Retain, easily recall, and use new information
_____ Demonstrate social maturity, especially in the home or community

Source: Castellano, Jaime A.; Diaz, Eva, *Reaching New Horizons: Gifted and Talented Education for Culturally and Linguistically Diverse Students*, © 2002. Reprinted and electronically reproduced by permission of Pearson Education, Inc., Upper Saddle River, NJ.

know they can learn in school. In contrast, the children who speak another language at home and have never been to school have no oral English to use as they learn the letters and sounds of written English. Bilingual instruction is the best strategy here.

Other questions to ask when considering a referral are: Were there any problems or complications during the mother's pregnancy? Has the child experienced any serious injuries or illnesses? Has the child moved around a great deal? Has the child had adequate opportunities to learn in a good bilingual or ESL program? Have the teachers who worked with the child been trained in teaching ESL? Is the student making progress, even if he or she is behind others the same age? Does the student have any talents or special skills to build on? These questions will help you determine if the student's difficulties are due to lack of learning opportunities, inadequate teaching, or a disability. No matter what the diagnosis—attention and appropriate teaching are needed. Students who have difficulties with English are much more likely to drop out of school (U.S. Department of Education, 2004).

Reaching Every Student: Recognizing Giftedness in Bilingual Students

Because they may be struggling with academic English, even though they are very knowledgeable, bilingual students may be overlooked for gifted and talented programs. A tenth-grade boy from Mexico, in the United States for 2 years, told an interviewer in Spanish:

High school is hard for me because my English is so limited. . . . There are times when I feel a lot of pressure because I want to say something, but I don't know how to say it. There are many times when the teacher is asking questions, I know the answer, but I am afraid that people might laugh at me. (Walqui, 2008, p. 104)

This student might well be gifted. To identify bilingual students who are gifted, you can use a case study or portfolio approach in order to collect a variety of evidence, including interviews with parents and peers, formal and informal assessments, samples of student work and performances, and student self-assessments. The checklist in Table 5.7, from Castellano and Diaz (2002), is a useful guide.

MyLab Education [Self-Check 5.6](#)

▼ SUMMARY

The Development of Language (pp. 206–214)

How are humans predisposed to develop language? What roles do culture and learning play? Cultures create words for the concepts that are important to them. Children develop language as they build on other cognitive abilities by actively trying to make sense of what they hear, looking for patterns, and making up rules. In this process, an innate language acquisition device (built-in biases and rules) may limit the search and guide the pattern recognition. Reward and correction play a role in helping children learn correct language use, but the child's thought processes are very important.

What are the elements of language? By age 5, most children have mastered almost all the sounds of their native language. In terms of vocabulary, we understand more words than we use. By age 6, children understand up to 20,000 words and use about 2,600 words. Understanding of words that express abstract ideas and hypothetical situations comes later as cognitive abilities develop. As children develop an understanding of grammar, they may apply new rules too widely, saying “broked” for “broken,” for example. Understanding the passive voice in syntax develops after understanding active voice.

What are pragmatics and metalinguistic awareness? Pragmatics is knowledge about how to use language—when, where, how, and to whom to speak. Metalinguistic awareness, knowledge about your own use of language and how language works, begins around age 5 or 6 and develops throughout life.

What are the most important skills that help literacy emerge? Research has identified two broad categories of skills that are important for later reading: (1) understanding sounds and codes such as knowing that letters have names, that sounds are associated with letters, and that words are made up of sounds; and (2) oral language skills such as

expressive and receptive vocabulary, knowledge of syntax, and the ability to understand and tell stories. One way to think about emergent literacy that captures both code and oral language skills for emergent literacy is the notion of inside-out skills (the ability to decode units of print into units of sound and units of sound into units of language) and outside-in skills and processes (the ability to understand those auditory derivations, which involves placing them in the correct conceptual and contextual framework). For bilingual Spanish-speaking students, growth in receptive language in Spanish or English predicts early reading outcomes. Parents and teachers can support emerging literacy by reading with children, retelling stories and talking about them, and limiting time spent watching television.

Diversity in Language Development (pp. 215–220)

What is involved in learning two languages? Children can learn two languages at once if they have adequate opportunities in both languages. There are cognitive advantages to learning more than one language, so it is valuable to retain your heritage language even as you learn another. The best time to learn accurate pronunciation is early childhood, but people of any age can learn a new language. Having overheard a language as a child can improve one's ability to learn that language as an adult. Even though the advantages of bilingualism seem clear, many children and adults are losing their heritage language. Rather than losing one language to gain another, the goal should be balanced bilingualism—being equally fluent in both languages. People who can communicate in both a spoken and a signed language or in two different signed languages are considered bilingual.

What does it mean to be truly bilingual? Some definitions of bilingualism focus exclusively on a language-based meaning: Bilingual people, or bilinguals, speak two languages. Other definitions are more rigorous and define bilinguals as adults who use their two languages effectively in their adult daily life, which includes being bicultural as well—moving back and forth between two cultures and two languages while still maintaining a sense of identity. Proficiency in a second language has two separate aspects: face-to-face communication (*contextualized language skills*) that take about 2 to 3 years in a good program to develop, and academic uses of language such as reading, writing, grammar, knowing specialized academic vocabulary, and understanding math problems, science charts, and study skills (known as *academic English*) that take about 6 to 9 years to develop. In fact, academic language should be considered a *new language* that people must learn in order to succeed in school. So all students, but especially those who may not speak formal English at home, must become bilingual and bicultural academically; they must learn the new ways of speaking and cultural rules required for school. Bilingual students also often struggle with social adjustment problems relating to biculturalism.

How do cultural differences affect bilingual students? Cultural differences might interfere with developing academic English and content understanding. For example, many Asian students come from a culture that believes asking the teacher questions is rude and inappropriate because questioning implies that the teacher has done a poor job of instruction. Teachers need to ask themselves why their students who are English language learners (ELLs) are not asking questions. Beliefs about learning shaped by culture and previous experiences in different kinds of classrooms may explain why students who are ELLs seem quiet and reluctant to speak in class. These students may also think that their teachers are not very good because the teachers do not explain everything. They also may strongly prefer memorization as a learning strategy if memorization was emphasized in their previous schools.

Dialect Differences in the Classroom (pp. 221–222)

What is a dialect? A dialect is any variety of a language spoken by a particular group. The dialect is part of the group's collective identity. Every person reading this book speaks at least one dialect, maybe more, because there is no one absolute standard English. Dialects differ in their rules about pronunciation, grammar, and vocabulary, but it is important to remember that these differences are not errors. Each dialect is logical, complex, and rule governed. There are even some differences in how males and females talk, called genderlects.

How should teachers take dialects into account? Teachers can be sensitive to their own possible negative stereotypes about children who speak a different dialect. Teachers also can ensure comprehension by repeating instructions using different words and by asking students to paraphrase instructions or give examples. The best teaching approach seems to be first to focus on understanding the students and to accept their language as a valid and correct system, but then to teach the alternative forms of English (or whatever the dominant language is in your country) that are used in more formal work

settings and writing so that the students will have access to a range of opportunities.

Teaching Immigrant Students (pp. 222–229)

Distinguish between the terms *immigrant* and *refugee*. Immigrants are people who voluntarily leave their country to become permanent residents in a new place. Refugees are a special group of immigrants who also relocate voluntarily, but they are fleeing their home country because it is not safe.

Distinguish between the “melting pot” and multiculturalism. Statistics point to increasing cultural diversity in American society. Old views—that minority group members and immigrants should lose their cultural distinctiveness and assimilate completely in the American “melting pot” or be regarded as culturally deficient—are being replaced by new emphases on multiculturalism, equal educational opportunity, and the celebration of cultural diversity.

What is Gen 1.5? Generation 1.5 are students whose characteristics, educational experiences, and language fluencies are somewhere in between those of students born in the United States and students who are recent immigrants. They were not born in the United States but have lived here most of their lives because they came with their families when they were young. The language spoken in their homes may not be English, but they often speak fluent conversational English, even if their academic English is not as well developed. They may tend to be “ear learners” who have mastered language by listening to and interacting with the language models around them.

Teaching Immigrant Students Who Are English Language Learners (pp. 230–236)

What is the terminology related to English learners? English learners sometimes are called limited English proficient (LEP). More often, these students are described as students who are English language learners (ELLs), because their primary or heritage language is not English. The classes devoted to teaching these students English are called English as a second language (ESL) classes. Limited proficiency in English often means lower academic achievement and poorer job prospects. So one issue around diversity in language development is how we should teach these students.

What are four general profiles of students who are ELLs? Students who are *balanced bilinguals* speak, read, and write well both in their first language and in English. *Monolingual/literate students* are literate in their native language (at or above grade level when working in their native language), but speak limited English. *Monolingual/preliterate students* are not literate. They may not read or write in their native language, or they may have very limited literacy skills. *Limited bilingual students* can converse well in both languages, but for some reason they have trouble learning academically. There may be underlying challenges such as learning disabilities or emotional problems.

What is bilingual education? Although there is much debate about the best way to help bilingual students master English, studies show it is best if they are not forced to abandon their first language. The more proficient students are in their first language, the faster they will master the second.

What is sheltered instruction? Sheltered instruction is one approach that has proved successful in teaching English and academic content. Sheltered instruction teaches content to students who are ELLs by putting the words and concepts of the content into context to make the content more understandable. Strategies include simplifying and controlling language, giving attention to the relevant grammar and forms of English—helping students “crack the code,” using visuals and gestures, and including real life supports and examples. In addition, there is an emphasis on student talk and discussion instead of the teacher doing all the talking. There are affective and emotional considerations for students who are ELLs. They may experience severe challenges and stress in school. They may feel that they don’t belong, that others are making fun of them, or just ignoring them. Building on students’ funds of cultural knowledge and using student-led conferences are ways to make classrooms more supportive and teaching more effective.

Special Challenges: Students Who Are English Language Learners with Disabilities and Special Gifts (pp. 236–239)

How do teachers deal with the special needs of students who are English language learners? As a teacher, one of your decisions will be whether to refer a struggling student who is an ELL for testing. Of course, the first step is to use the best teaching approaches, incorporating sheltered instruction to develop both subject matter learning and English language development. But if progress seems much slower than usual, you might refer the student for observation or testing. No matter what the diagnosis—attention and appropriate teaching are needed. Students who have difficulties with English are much more likely to drop out of school. And because language differences can mask giftedness, teachers should make special efforts to identify bilingual students and students who are ELLs who have gifts and talents.

▼ CONNECT AND EXTEND TO LICENSURE

MULTIPLE-CHOICE QUESTIONS

- Detlev (age 3), his brother Carl (age 6), and their parents have recently moved from Germany to Great Britain. The family has never used English to communicate with one another. At home, in an effort to acquire mastery over the English language more rapidly, the family has decided to converse in English on a daily basis. However, they have come across a lot of colloquialism and grammatically incorrect phrases. Detlev and Carl are both struggling at school. What could be the reason?
 - Generation 1.5 students often have difficulty learning to read and write accurately in English.
 - The boys have some learning disability.
 - The school environment is too demanding for the boys.
 - The boys' parents have exceedingly high scholastic expectations.
- Tom is a two-year-old with reasonably good command of English. His family has a fox terrier at home. On a road trip to the countryside, they passed a pasture that had cows grazing near the roadside. Tom squealed, pointed to the pasture, and loudly announced to his mother that there were many large dogs in the field. What caused Tom's error in calling a cow a dog?
 - Tom could not see the cows properly, and hence, assumed they were dogs.
 - Tom is lagging behind in his language development.
 - Tom provided a label to refer to a class of similar objects and, thus, applied a built-in bias.
 - Tom's parents have not taught him the difference between a cow and a dog.
- Once Mr. Heney learned that his Asian ELL students consider it rude to ask the teacher questions because questioning implies that the teacher has done a poor job of teaching, he could generalize to which one of the following assumptions?
 - If his English language learners are not asking questions, he needs to ask them why.
 - He should always quiz his Asian students because they may not be able to understand.

- Asian students are always very polite, but their silence can mean they do not respect him as a teacher.
 - Mr. Heney cannot make any generalizations about culture and learning.
- One important way in which a teacher can motivate students is to show an interest in their lives. All but which one of the following are appropriate motivational strategies that demonstrate an interest in the lives of students from diverse backgrounds?
 - Incorporate students' traditions into writing and language arts activities.
 - Show respect for students' diversity by learning some key words in their language.
 - Ask students to write a three-page essay in English about their family.
 - Inquire about students' past experiences in their native country.

CONSTRUCTED-RESPONSE QUESTIONS

Case

Jacinto Ngimbi was teaching for 12 years in Luanda, and was consistently voted the best teacher in his school. He started teaching high school this year in Cabinda. He was very excited to be teaching in a different area of Angola. However, on his first day of teaching he became despondent. The students in his class were communicating in a dialect that was different from the Portuguese Jacinto was used to. He was finding it difficult to understand his students. He also noticed that his students did not understand the concepts of chemistry he was trying to teach. Whenever he asked his students questions, they would either not answer or answer incorrectly.

- How could speaking a different dialect affect the learning of chemistry concepts being taught in Portuguese?
- What can teachers such as Jacinto Ngimbi do when their students speak in a different dialect?

MyLab Education **Licensure Exam**

▼ WHAT WOULD THEY DO?

TEACHERS' CASEBOOK: Cultures Clash in the Classroom

Here is how several expert teachers said they would establish positive relationships with the class described at the beginning of the chapter that included African American, Asian, and Latino/a students who did not get along.

JENNIFER PINCOSKI • Learning Resource Teacher: K–12
Lee County School District, Fort Myers, FL

The teacher has difficulty connecting with his/her students because the cultures are so different and the groups don't understand each other. The teacher's discomfort is evident, which is problematic because as the classroom leader, a teacher's attitude and behavior set the tone for everyone. Establishment of an inclusive and accepting learning environment starts at the top. It is important to model understanding and acceptance by respecting students as individuals, celebrating their differences, and showing a genuine interest in their lives.

This is a good opportunity to get to know students on a more personal level. After assigning a quiet, independent task, the teacher can use this time to have brief conferences with each student one on one. Conferences should focus on becoming acquainted with the students, learning about their interests, and discussing goals. Not only does this help develop positive relationships, it also provides important information that can be used to plan future lessons and activities.

Furthermore, in an effort to get students from different cultures to interact, the teacher may need to change the physical arrangement of the room and/or reassign seats. Rather than allowing students to choose their own groups, the teacher could either assign groups randomly or purposefully group students according to strengths, interests, learning styles, and so on. Groups should change frequently, and assignments should be thoughtfully designed to complement students' individual characteristics.

LAUREN ROLLINS • FIRST-GRADE TEACHER
Boulevard Elementary School, Shaker Heights, OH

At the beginning of each school year, I set aside a significant amount of time to get to know my students, for them to get to know each other, and for them to get to know me. This is an integral part of building a classroom community. Familiarization with each group's culture is mandatory to achieve a successful outcome. It is also important that the groups of students learn to have mutual respect for each other. This is so important that it is worth suspending the curriculum until these goals are met. One activity would be to invite the students to share their backgrounds and cultures in a "show and tell" situation. Another activity would be to create "compliment charts" for each other. The students would write compliments, positive statements, and

qualities that they like about each other on the charts. At the end of the activity, each student will walk away feeling respected and appreciated. It is a "feel good" activity and a big step toward respecting and appreciating the members of the classroom.

LINDA SPARKS • FIRST-GRADE TEACHER
John F. Kennedy School, Billerica, MA

Students are very quick to pick up on what a person thinks about them or how someone feels about them. I have not had this specific incident happen in my class, because I am in an elementary school. But I believe this can happen at any level, especially when the teacher feels uncomfortable in the setting. Students pick right up on how a teacher feels about them. They need to be respected in order to learn to be respectful, while building their trust and confidence. Once that trust is earned, the students are more willing to participate in activities in the classroom. I would have to do some flexible grouping as simple as, "If you have green sneakers on, move to the left corner." They are not moving because they are of a specific ethnic group. I always have a jar with these quirky questions to move kids around, especially when I am changing desks. This also will maximize instruction because now they want their group to beat out their friends' group. When this happens, students will begin to get along socially while academic needs are being met.

PAULA COLEMERE • Special Education Teacher • English, History
McClintock High School, Tempe, AZ

My first goal is always to create a safe learning environment for my students. With underlying issues based on racial divisions in a class, it would be difficult for students to come to class prepared to learn. The hostility needs to be erased in this class. To work toward this goal, I would have the class do a team-building activity. This activity would be built to show students that no matter how they look, they are much more alike than different. There is an activity I have done where students walk to the center line if they have ever experienced something. It starts simple, but gets deeper. For example, the facilitator might say, "Go to the center line if you know someone who has been murdered." Sadly, many students have experienced this, and they will see they are not alone. Following this activity, I would have a discussion with the students about leaving our differences at the door. This is a teachable moment, as we will come across people throughout our lives that we don't like or who are different from us, but we have to find a way to make the relationship work to hold a job.

chapter six

CULTURE AND DIVERSITY

TEACHERS' CASEBOOK: White Girls Club

You teach in a seemingly homogeneous primary school. In fact, most of your kindergarten and first-grade students are middle- or upper middle-class and White. In January, a new student came to your school—the daughter of an African American professor who recently arrived to teach at the nearby college. After a few weeks, you notice that the new student is not being included in many activities. She sits by herself in the library and plays alone at recess. No one eats with her at lunch, and at recess she is the last to be chosen for any team. This is troubling enough, but then one day you overhear two of your higher-achieving girls talking about their “White Girls Club.”

CRITICAL THINKING

- Would you investigate to learn more about this “Club”? How?
- If you found that your students had created a club that excluded non-White students, what would you do?
- If you teach older students, what can you do about student groups that define themselves by who *cannot* be members?

WHAT WOULD YOU DO?

Julias/Shutterstock

OVERVIEW AND OBJECTIVES

The cultural composition of American classrooms is constantly evolving. The same can be said for classrooms in many countries today. In a talk to the American Educational Research Association, Frank Pajares, one of the wisest educational psychologists I know, said, “The critical questions in education involve matters that cannot be settled by universal prescription. They demand attention to the cultural forces that shape our lives” (Pajares, 2000, p. 5). I believe he is right. In this chapter, we examine the many cultures that form the fabric of our society. We begin by considering some statistics about diversity in schools and then meet two individuals whose stories bring the statistics to life—you met another one, Felipe, in Chapter 5. Next, we trace the schools’ responses to different ethnic and cultural groups. With a broad conception of culture as a basis, we then examine three important dimensions of every student’s identity: social class, race/ethnicity, and gender and sexuality. Then, we turn to a consideration of multicultural education, a general process of school reform that embraces diversity, and we look at approaches to creating culturally compatible classrooms. The last section presents four general principles for teaching every student. By the time you have completed this chapter, you should be able to:

- Objective 6.1 Describe the meaning of culture and discuss how cultural diversity in American schools today is related to learning and teaching.
- Objective 6.2 Discuss what defines social class and socioeconomic status, including how SES differences relate to school achievement.
- Objective 6.3 Explain how race, ethnicity, prejudice, discrimination, and stereotype threat might affect student learning and achievement in schools.
- Objective 6.4 Describe the development of gender, gender identity, and sexual orientation and discuss their role in teaching and learning.
- Objective 6.5 Define multicultural education and apply research on diversity to the creation of culturally compatible classrooms.

TODAY'S DIVERSE CLASSROOMS

In this text we take a broad interpretation of cultural diversity. In this chapter, we will examine social class, race, ethnicity, gender, and sexual orientation as aspects of diversity. We begin with a look at the meaning of culture. Many people associate this concept with “cultural events” such as enjoying art galleries, museums, Shakespeare festivals, classical music concerts, and so on. But culture has a much broader meaning; it embraces the whole way of life of a group of people.

STOP & THINK Take a quick break from reading, and turn on the television. (Don't do this if you won't come back to reading until next Tuesday!) Find a channel with commercials. (I know, it's harder to find one without.) Listen to about 15 commercials. For each one, is the voice or the character in the ad old or young? Economically privileged or poor? Male or a female? What is the character's ethnicity or race? Do a quick tally of how many instances you observe in each category. •

American Cultural Diversity

There are many definitions of **culture**. Most include some or all of the following: the knowledge, skills, rules, norms, practices, traditions, self-definitions, institutions (educational, legal, communal, religious, political, etc.), language, and values that shape and guide beliefs and behavior in a particular group of people as well as the art, literature, folklore, and artifacts produced and passed down to the next generation (Banks & Banks, 2016; Cohen, 2009, 2010). The group constructs a culture—a program for living—and communicates the program to members. This communication is for the most part *tacit*—understood or implied without being explicitly stated. Cultural groups can be defined along regional, ethnic, religious, racial, gender, social class, or other lines. Each of us is a member of many groups, so we all are influenced by many different cultures. Sometimes, these influences are incompatible or even contradictory. For example, if you are a feminist but also a Roman Catholic, you may have trouble reconciling the two different cultures' beliefs about the ordination of women as

priests. Your personal belief will be based, in part, on how strongly you identify with each group.

Many different cultures thrive within every modern country. In the United States, students growing up in a small rural town in the Great Plains are part of a cultural group that is very different from that of students in a large Northeastern urban center or students in a Texas suburb. Within those small towns in the Great Plains, the son or daughter of a convenience store clerk grows up in a different culture from the child of the town doctor or dentist. Individuals of African, Asian, Hispanic, Native American, or European descent have distinctive histories and traditions. Everyone living within a particular country shares many common experiences and values, especially because of the influence of the mass media. But other aspects of their lives are shaped by differing cultural backgrounds, and increasingly by their “friend” networks on social media.

FIGURE 6.1

CULTURE AS AN ICEBERG

Just as most of the iceberg is out of sight and below the water line, so are most cultural differences out of conscious awareness. It is the out-of-awareness differences that are often the cause of misunderstandings and conflicts.

MyLab Education Podcast 6.1

In this podcast, textbook author Anita Woolfolk talks about how important it is for teachers to understand and accept cultural differences in their students. Listen to find out how cultural awareness can prevent conflicts between students, teachers, and parents.

Culture The knowledge, values, attitudes, and traditions that guide the behavior of a group of people and allow them to solve the problems of living in their environment.

Culture has been compared to an iceberg. One third of the iceberg is visible; the rest is hidden and often unknown. The visible signs of culture, such as costumes and marriage traditions, reflect only a small portion of the differences among cultures, as you can see in Figure 6.1.

Many cultural differences exist “below the surface.” They are implicit, unstated, even unconscious biases and beliefs (Kahneman, 2011; Sheets, 2005). Cultures differ in rules for conducting interpersonal relationships, for example. In some groups, listeners give a slight affirmative nod of the head and perhaps an occasional “uh huh” to indicate they are listening carefully. But members of other cultures listen without giving acknowledgment, or with eyes downcast, as a sign of respect. In some cultures, high-status individuals initiate conversations and ask the questions, and low-status individuals only respond. In other cultures, the pattern is reversed.

Cultural influences are widespread and pervasive. Some psychologists have even shown that culture can determine how a group defines intelligence (Nisbett, 2009). For example, physical grace is essential in Balinese social life, so the ability to master

physical movements is a mark of intelligence in that culture. Manipulating words and numbers is important in Western societies, so in these cultures such skills are indicators of intelligence (Gardner, 2011). Even symptoms of psychological disorders are affected by culture. In industrialized cultures where cleanliness is emphasized, people with obsessive-compulsive disorders often become obsessed with cleaning their hands, whereas in Bali, where social networks are emphasized, people with obsessive-compulsive disorders often become obsessed with knowing all the details about the lives of their friends and family—their social network (Lemelson, 2003).

Let's get more specific about cultural diversity by meeting two students.

Meet Two More Students

In Chapter 1, you read some statistics about students in America and saw that classrooms are becoming more diverse. But teachers do not work with statistics; they work with students—unique individuals, such as Felipe Vargas, the fifth-grader you met in Chapter 5. In this section, Nancy Knapp from the University of Georgia invites us to meet two more individuals. These students are not specific people; they are composites of the characteristics of real people Nancy has known and taught. The names and schools are fictional, but the descriptions of these students' lives are very real.

Ternice Mattox is a seventh-grader who lives with her mother and three younger siblings in a large city in the Northeast. Her mother works the 7:00 to 3:00 shift at a dry-cleaning plant and then cleans offices some nights and weekends to make ends meet, so Ternice gets her brothers and sister up and ready for school every day, feeds them dinner when they get home, and makes sure they do their homework at night; she has been doing this since she was 10.

School hasn't ever been very hard for Ternice. In elementary school she usually got Bs, but never really liked school until sixth grade when her English teacher "let you write about whatever you wanted, even your own life; and she didn't count off for every mistake right away, but let you work with her and with the other kids until you had a final copy you could be really proud of." Ternice found out that she really enjoyed writing and was good at it too. She talked so much in English class that Anthony Bailey criticized her about "actin' so White." Ternice got mad; it really bothered her. She and Anthony kind of go together, and she likes him a lot. Her teacher wants her to take some tests, to see if she can get into the program for students with gifts and talents, but Ternice is not so sure. Even if she got in, she's afraid she wouldn't know anyone; almost all the kids in "gifted" are White, and the few Black kids are from another part of town. Besides, her friends might not like it, especially Anthony. Her mama wants her to try and says there's no telling where she can go from there, but Ternice doesn't want to go anywhere that's away from all her friends. Still, she wishes she could have more classes like her English class last year.

Jessie Kinkaid is a junior at Red Falls High School in Wisconsin. She lives with her mother, who works as a doctor's receptionist, in a small house in town. Her father lives just outside of town with his second wife and Jessie's 3-year-old half-brother, so she sees him pretty often.

Jessie is in the vocational track at school and mostly makes Cs, with a few Ds. Once in a while, she fails a course, but she'll have enough credits to graduate by the end of next year, which is all she really cares about. Her home economics teacher says she has a real flair for cooking and wants Jessie to bring up her grades so she can apply to chef's school. Jessie likes to cook and knows she's good at it, but doesn't see any point in going to more school. She's only graduating to please her parents; she knows what she's going to do with her life. After graduation she's going to get a job in town somewhere for a couple years to save up some money, and then she'll marry Walter Aiken. She and Walt have been going together since she was a freshman and he was a junior. Walt started this year at UW-Platteville to get a degree in animal science, and they plan to wait until he is finished before they get married. Then they'll move into the small house on the Aiken's farm until Walt's dad is ready to retire, probably in another 3 or 4 years. Then Walt will take over the farm, and they'll move into the big house; Jessie hopes they'll have at least one child by then.

So Jessie doesn't see any point in worrying about her grades, as long as she graduates. Her father agrees it would be foolish to waste time and money on extra schooling she'll never use. Jessie's mother, who left school at 17 to marry, is the one urging Jessie to think about going on. She says she just wants Jessie to "keep all her options open."

Felipe, Ternice, and Jessie are just three students, and there are millions more—unique collections of abilities and experiences. They speak different languages, have different ethnic and racial backgrounds, and live in different kinds of communities. Some come from families in poverty, others from families with power and privilege—but all face challenges in their education. For the remainder of the chapter, we look at the dimensions of cultural differences in schools today.

Cautions: Interpreting Cultural Differences

Before we discuss cultural differences, two cautions are necessary. First, we will consider social class, ethnicity, race, and gender separately, because much of the available research focuses on only one of these variables. Of course, real children are not just African American, or middle class, or male; they are complex beings and members of many groups, just like the three students you met earlier. The result is a fascinating tapestry of cultural intersectionality. **Intersectionality** refers to our overlapping, intersecting social identities (gender, sexual orientation, class, ethnicity, religion, age, etc.) that shape each of us in unique ways (Rosenthal, 2016). For example, students who experience homelessness are disproportionately from ethnic minority groups, and **LGBTQ** (lesbian, gay, bisexual, transgender, and questioning) students are at greater risk of homelessness than are heterosexual youth (Coker, Austin, & Schuster, 2010). A whole chapter could be devoted to the intersections of these various cultural group memberships and how they influence learning and teaching. We will discuss just a few examples of intersecting identities, but encourage you to consider your own examples.

The second caution is that group membership is not destiny. Just knowing a student is a member of a particular cultural group does not define what that student is like. People are individuals. Say, for example, a student in your class consistently arrives late. It may be that the student has a job before school, must walk a long distance, is responsible for getting younger siblings to school like Ternice, or even that he or she dreads school. We cannot focus on group membership as the sole explanatory factor of any behavior; humans are much too complicated!

STOP & THINK Stop here for a moment and think of three to five cultural groups to which you belong (gender, sexual orientation, class, ethnicity, religion, age, etc.). How do the intersections of your memberships influence your interactions with others? How might your own cultural heritage and chosen cultural affiliations affect how you see yourself and what you do? What have been the major advantages of your group affiliations? What, if any, disadvantages have you experienced? •

CULTURAL CONFLICTS AND COMPATIBILITIES. The differences between cultures may be very obvious, tip-of-the iceberg characteristics such as holiday customs and dress, or they may be very subtle, below-the-surface differences such as how to get your turn in conversations. When subtle cultural differences meet, misunderstandings and conflicts are common. These conflicts can take place when the values and competencies of the dominant, mainstream culture are used to determine what is considered "normal" or appropriate behavior in schools. In these cases, children who have been socialized in a different culture may be perceived as acting inappropriately, not following the rules, or being rude and disrespectful.

Rosa Hernandez Sheets (Sheets, 2005) describes a 5-year-old Mexican American girl who tried to bring a bread roll, part of her school cafeteria lunch, home to give to her little brother every day. Her parents were proud of her for sharing, but the school officials made her throw the roll away, because it was against school rules to take food

Connect and Extend to PRAXIS II®

Cultural and Gender Differences in the Classroom (III, B)

What are the sources of possible miscommunication between students and teachers in the classroom because of cultural or gender differences? Identify steps a teacher can take to minimize such problems.

Intersectionality Our overlapping, intersecting social identities (gender, sexual orientation, class, ethnicity, religion, age, etc.) that shape each and every one of us in unique ways.

LGBTQ (lesbian, gay, bisexual, transgender, and questioning) Individuals whose sexual orientation is lesbian, gay, bisexual, or transgendered, or who are currently questioning their sexual orientation.

from the cafeteria. The girl was conflicted about following school rules versus honoring her family's cultural values. The teacher in this case solved the problem by talking to the cafeteria cook, putting the roll in a plastic bag, and placing the bag in the girl's backpack to be taken home after school.

Not all cultural differences lead to clashes in school, however. For example, compared to other ethnic groups, Asian Americans have the highest graduation rates from high school, college, and graduate school—so sometimes they are labeled as “model minorities” (Lee, 2008). Is this fair?

MyLab Education Video Example 6.1

As this teacher learned from a student, respecting a student's culture is very different than expecting a student to have particular interests, skills, or behaviors simply because he or she has a particular cultural background.

DANGERS IN STEREOTYPING. There are dangers in stereotyping both Asians and Asian Americans as model students—quiet, hardworking, and passive. Acting on these stereotypes can reinforce conformity and stifle assertiveness. Stacey Lee (2008) describes another stereotype confronting Asian Americans. They are seen as perpetual foreigners. No matter how many decades their families have lived in America, even fourth- or fifth-generation Asian American students are not perceived as “real” Americans (Lee & Zhou, 2015). In fact, Lee's research shows that teachers tend to refer to these students as “Asian,” not “Asian American” or “American.” That would be like calling me a German student because my great-grandfather came to Wisconsin from Germany. I was born in Texas, and my first-hand knowledge of German culture is limited to my grandmother's recipe for pfeffernüsse—excellent, by the way.

Too often, students take these stereotypes to heart and feel “foreign” even in the country of their birth—America. One high school student told Lee (2008), “Watching MTV affected the way I acted very much. I wanted to be more Americanized. I changed my hair color. I got colored contact lenses” (p. 78). Later in this chapter, we explore ways to make classrooms more compatible with the cultures of students. First, however, we need to examine some of the effects of cultural conflicts, prejudice, and discrimination on student well-being and achievement.

MyLab Education Self-Check 6.1

ECONOMIC AND SOCIAL CLASS DIFFERENCES

Even though most researchers would agree that social class is one of the most meaningful cultural dimensions in people's lives, those same researchers have great difficulty defining *social class* (Liu et al., 2004; Macionis, 2013). Different terms are used—social class, socioeconomic status, economic background, wealth, poverty, capital, or privilege. Some people consider only economic differences; others add considerations of power, influence, mobility, control over resources, access to opportunities, and prestige.

Connect and Extend to PRAXIS II®

Economic Conditions/ Socioeconomic Status (SES) (IV, B2)

Be aware of the possible effects of SES on student achievement. Consider what steps teachers can take to minimize those effects.

Social Class and Socioeconomic Status

In modern societies, levels of wealth, power, and prestige are not always consistent. Some people—for instance, university professors—are members of professions that are reasonably high in terms of social status but provide considerably less wealth or power (believe me). Other people have political power even though they are not wealthy, or they may be members of the elite social register in a town, even though their family money is long gone. Most people are generally aware of their social class; that is, they perceive that some groups are above them in social class and some are below. They may even show a kind of “classism” (like racism or sexism), believing that they are “better” than members of lower social classes and avoiding association with them. For example, Marissa, a member of the most popular and privileged clique in her high school, described the “grits”—the least popular group:

Grits are poor. I think they mostly live in the country. We—[quickly correcting herself] some of my friends call them hicks or rednecks. I guess most live on the Hill—that's

TABLE 6.1 • Selected Characteristics of Different Social Classes

	UPPER CLASS (OWNING CLASS)	UPPER MIDDLE CLASS (MANAGERIAL CLASS)	MIDDLE CLASS	WORKING CLASS	LOWER CLASS
Income	\$200,000 to billions	\$114,000–\$200,000	\$48,000–\$114,000	\$27,000–\$48,000	Below \$27,000
Occupation/ Source of Money	Family money, “old money,” investments, CEO	Corporate, professional, income earned in some way	White-collar, skilled blue-collar	Blue-collar	Minimum wage, unskilled labor
Education	Home-schooled, tutors, prestigious private schools and colleges	Prestigious colleges and graduate schools	High school, college, or professional school	High school	High school or less
Home Ownership	Several homes, private jets for transportation	At least one home	Usually own home	About half own a home	Uncommon
Health Coverage	Full	Full	Usually	Limited	Uncommon
Neighborhoods	The most exclusive	Exclusive or comfortable	Comfortable	Modest	Deteriorating
Afford Children’s College	Easily	Usually	Seldom	Rarely	Uncommon
Political Power	National (perhaps international), state, local	National, state, local	State or local	Limited	No

Note: All descriptions are rough categorizations. Many exceptions can occur within each category according to individuals and context. For example, income markers differ by number in household and geographic region. In very expensive areas such as Honolulu, it may take at least \$150,000 for a family of three to be in the lower middle class.

Source: Information from Macionis, J. J. (2013). *Society: The basics* (12th ed). Upper Saddle River, NJ: Pearson and Gorski, P. (2013). *Reaching and teaching students in poverty: Strategies for erasing the opportunity gap*. New York, NY: Teachers College Press.

over on the west side of town. It’s the slums. Grits smoke, do drugs, dress grungy. They have those hick accents. They usually get bad grades. They don’t like school so I think they drop out a lot. They don’t really fit in. They are troublemakers. I don’t see them much; they aren’t in any of my classes. (Brantlinger, 2004, pp. 109–110)

In addition to social class, there is another way of thinking about differences that is commonly used in research. Sociologists and psychologists combine variations in wealth, power, control over resources, and prestige into an index called **socioeconomic status (SES)**. In contrast to social class, most people are not conscious of their SES designation. SES is usually ascribed to people by researchers; different formulas for determining SES might lead to different categorizations (Macionis, 2013; Sirin, 2005). No single variable, not even income, is an effective measure of SES. Most researchers identify four general levels of SES: upper, middle, working, and lower classes. The main characteristics of these four SES levels in the United States are summarized in Table 6.1. According to the Pew Research Center (2016), although roughly half of American adults lived in middle-income households in 2014, that number is shrinking as the number of wealthy and poor households in America increases. As you watched the commercials in the *Stop & Think* activity at the beginning of this chapter, how many people did you see who appeared to be in the lower-class SES?

Socioeconomic status (SES) Relative standing in the society based on income, power, background, and prestige.

Extreme Poverty: Homeless and Highly Mobile Students

When families live in extreme poverty, they sometimes lack even a stable home. In the 2013–2014 school year, more than 1.3 million students were homeless in the United States (National Center for Homeless Education, 2015). Between 2011 and 2014, the number of homeless students increased by 10% to 25% in 37 states. Students who are homeless or who move very often are at additional risk for a range of physical, social, and learning difficulties. For example, even after taking many other risk factors and income levels into account, students who moved three or more times during a school year were 60% more likely to repeat a grade (Cutuli et al., 2013). According to the National Center on Family Homelessness, 75% of elementary students and 85% of high school students who were homeless performed below grade level in reading and math. Homelessness and high mobility contribute to chronic risks and problems in school, problems that are difficult to overcome.

Even with such risks, many of these students are resilient in the face of problems. J. J. Cutuli and his colleagues (2013) analyzed the math and reading test scores of over 26,000 students from third through eighth grades and found that 45% of the homeless and highly mobile students achieved in the average or better range across time, in spite of their challenges. The researchers concluded that factors such as effective parenting, student self-regulation skills (see Chapter 11), academic motivation (see Chapter 12), and the quality of teaching and teachers' relationships with students (see this whole book) supported resiliency for these students. The early years in school are particularly important. Homeless students who develop reading and self-regulation skills in the early grades are more likely to be successful throughout school (Buckner, 2012). Because self-regulation is so important for everyone, we will spend quite a bit of time in Chapter 11 exploring how to help students develop these skills.

Poverty and School Achievement

About 21% of Americans under the age of 18 live below the poverty level: \$24,600 annual income for a family of four (Jiang, Ekono, & Skinner, 2016). In fact, over 9% of all children live in extreme poverty, existing on about \$2 a day. For a while, there were improvements. In 2000, the number of families in poverty was the lowest in 21 years, but since then rates have been rising, particularly for African American children (Bishaw, 2013). If we add children living in low-income families (earning about \$48,000 for a family of four), then 44% of all children in the United States live in low-income or poor families and 30 million students qualified for free or reduced-price lunches at school in 2016 (Jiang et al., 2016; U.S. Department of Agriculture, 2016). To meet some of these students and get a glimpse of their lives, read *Fire in the Ashes: Twenty-Five Years Among the Poorest Children in America*. Jonathan Kozol (2012) tells the amazing stories, trials, and triumphs of children living amid extreme poverty. Every teacher should read this book.

The absolute number of children living in poverty is similar for non-Hispanic White children (5 million), Latina/o children (6 million), and African American children (5 million). But the rate of poverty is much higher for African American, Latino, and Native American children—43% of African American and 34% of Latino children lived in poverty in 2012, whereas 15% of Asian and 13% of non-Hispanic White children were poor (Children's Defense Fund, 2015). Contrary to many stereotypes, the *absolute number* of poor children living in suburban and rural areas is greater than in central cities. But poverty *rates* are high in urban schools.

The average correlation between SES and achievement tests is moderate, about .30 to .40 (Sackett, Kuncel, Arneson, Cooper, & Waters, 2009; Sirin, 2005). In general, students of all ethnic groups with high SES show higher average levels of achievement on test scores and stay in school longer than students with low SES, and this difference widens with the student's age from 7 to 15 (Berliner, 2005; Cutuli et al., 2013). And the longer the child is in poverty, the stronger the impact is on achievement. For example, even when we take into account parents' education, the chance that children

FIGURE 6.2

TRENDS IN READING ACHIEVEMENT FROM THIRD THROUGH EIGHTH GRADE FOR STUDENTS IN SEVERAL INCOME RISK GROUPS

Note: General = students who were never a part of any of the risk groups; HHM = homeless/highly mobile.

Source: Cutuli, J. J., Desjardins, C. D., Herbers, J. E., Long, J. D., Heistad, D., Chan, C-K, Hinz, E., & Masten, A. S. (2013). Academic Achievement Trajectories of Homeless and Highly Mobile Students: Resilience in the Context of Chronic and Acute Risk. *Child Development*, 84, p. 851. Reproduced with permission of John Wiley & Sons, Inc.

will be retained in grades or placed in special education classes increases by 2% to 3% for every year the children live in poverty (Ackerman, Brown, & Izard, 2004; Bronfenbrenner, McClelland, Wethington, Moen, & Ceci, 1996). Figure 6.2 shows the trends in reading achievement from third through eighth grade for students in several income risk groups (homeless/highly mobile, free lunch, reduced cost lunch) compared both to the national average for those grades and to students who were not ever a part of any of these risk groups (labeled “general” in the figure). You can see that the growth rates are similar, but these groups begin at different levels in third grade. This is another reason early interventions (preschool and primary school) are especially important for students placed at risk.

One troubling trend is that the achievement gap is growing between children from privileged families (income at the ninetieth percentile) and children from poor families (income at the tenth percentile). This gap is 30% to 40% greater for children born in 2001 compared to children born in 1976. These increasingly dramatic income differences between wealthy and poor have led to greater segregation of low-income children in lower-quality schools. Economic resources available to wealthy children allow them to reap tremendous advantages from informal learning opportunities, such as travel, specialized summer camps, and tutoring services—resources that poor families can’t afford (Berliner, 2013; Reardon, 2011). This has led some researchers to refer to differences in

the educational performance of rich and poor students as an “opportunity gap” rather than an achievement gap (Gorski, 2013; Milner, 2010; 2015).

What are the effects of low SES that might also contribute to the lower school achievement of these students? No single cause is to blame (Evans, 2004). Poor health care for mother and child, dangerous or unhealthy home environments, limited resources, family stress, interruptions in schooling, exposure to violence, overcrowding, homelessness, discrimination, and other factors lead to school failures, low-paying jobs—and another generation born into poverty. Numerous scholars have offered other possible explanations (Evans, 2004; Gorski, 2013; Jensen, 2016; McLoyd, 1998). Let’s take a closer look at some of them.

HEALTH, ENVIRONMENT, AND STRESS. The negative effects of poverty begin even before a child is born. Families in poverty have less access to good prenatal and infant health care and nutrition. Over half of all adolescent mothers receive no prenatal care at all. Poor mothers and adolescent mothers are more likely to have premature babies, and prematurity is associated with many cognitive and learning problems. Children in poverty are more likely to be exposed to both legal drugs (nicotine, alcohol) and illegal drugs (cocaine, heroin) before birth. Children whose mothers take drugs during pregnancy can have problems with organization, attention, and language skills.

Poor children are four times as likely to experience chronic stress due to evictions, lack of food, overcrowding, or utility disconnections. Increased stress is related to increased school absences, decreased attention span and concentration ability, problems with memory and thinking, reduced motivation and effort, increased depression, and reduced neurogenesis (growth of new brain cells) (Evans & Kim, 2013; Jensen, 2013). In the early years, children in poverty experience higher levels of stress hormones than children in middle-class and wealthy families. High levels of these hormones can interfere with the flow of blood in the brain, decrease the development of synaptic connections, and deplete the body’s supply of tryptophan, an amino acid that calms impulsive and violent behaviors (Hudley & Novak, 2007; Richell, Deakin, & Anderson, 2005; Shonkoff, 2006). As they grow, poor children breathe more polluted air and drink more contaminated water—remember the scandal surrounding the water in Flint, Michigan. Poor children are at least twice as likely as non-poor children to suffer lead poisoning, which is associated with lower school achievement and long-term neurological impairment (Evans, 2004; McLoyd, 1998).

LOW EXPECTATIONS—LOW ACADEMIC SELF-CONCEPT. Poor students are also at risk of being stigmatized by their teachers and peers. For example, students from homes with limited resources may wear older clothes, speak in a certain dialect, or be less familiar with books and school activities. Their teachers and other students may in turn believe that these students are not bright. The teacher may avoid calling on them, assuming they don’t know the answer, set lower standards, place them in lower-ability groups, and accept poor work. Thus, low expectations become institutionalized, and the educational resources provided to these children are minimal and inadequate (Borman & Overman, 2004). Low expectations, along with a lower-quality educational experience, can lead students to a sense of learned helplessness, described in Chapter 4. Students with low SES, particularly those who also encounter racial discrimination, may decide that school is a dead end. Without a high school diploma, these students find few rewards awaiting them in the work world. Many available jobs barely pay a living wage. In his 2015 book, *Rac(e)ing to Class*, Richard Milner describes the ways in which the intersection of poverty and race have led to chronic inequalities in the educational opportunities of poor students of color.

PEER INFLUENCES AND RESISTANCE CULTURES. Students who attend schools where most of their peers are from middle- and high-income families are 68% more likely to attend college compared to students in schools where most of the students are from low-income homes. Even after controlling for many possible causes, Gregory

Palardy (2013) concluded that peer influences were the strongest predictor of this difference in college attendance. Students in high-poverty schools are much less likely to have friends who plan to attend college and much more likely to have friends who drop out of school.

Some researchers have suggested that certain students from low SES backgrounds may cope with the inequities around them by becoming part of a **resistance culture**. To members of this culture, making it in school means selling out and trying to act “middle class.” To maintain their identity and their status within the group, these students may cope by rejecting the behaviors that would make them succeed in school—studying, cooperating with teachers, even coming to class (Bennett, 2011; Ogbu, 1987, 1997). This is an understandable reaction from students who might view such attempts as futile in an oppressive or discriminatory system. John Ogbu linked identification with a resistance culture to poor Latino American, Native American, and African American groups, but similar reactions have been noted for poor White students both in the United States and in England and also in high school students in Papua New Guinea (Woolfolk Hoy, Demerath, & Pape, 2002).

This is not to say that all or even most students with low SES resist achievement. Many young people are high achievers in spite of either their economic situation or negative peer influences (O'Connor, 1997). And we should not forget that some aspects of schooling—competitive grading, public reprimands, stressful testing and assignments, and repetitive work that is too hard or too easy—can (and probably should) encourage resistance in all students (Okagaki, 2001). Focusing solely on students' resistance (or their lack of resilience) is a way of blaming students for their lower achievement; instead, educators should focus on making school an inclusive place that does not invite resistance from anyone (Stinson, 2006). One way to do this is by realizing how our own cultural background, socialization, and rigid stereotypes “might hinder our abilities to connect with low-income families, or any families, in the most authentic, open way” (Gorski, 2013, p. 59). In Gorski's words, educators need to become “equity literate.”

HOME ENVIRONMENT AND RESOURCES. Families in poverty seldom have access to high-quality preschool care for their young children—the kind of care that enhances cognitive and social development (Duncan & Brooks-Gunn, 2000; Vandell, 2004). Poor children read less and spend more time watching television; they have less access to books, computers, libraries, and trips—opportunity gaps again (Kim & Guryan, 2010). Again, not all low-income families lack resources. Many families provide rich learning environments for their children. When parents of any SES level support and encourage their children—by reading to them, providing books and cognitively stimulating toys, taking the children to the library, making time and space for learning—the children tend to become better, more enthusiastic readers (Cooper, Crosnoe, Suizzo, & Pituch, 2010). Home and neighborhood resources seem to have the greatest impact on children's achievement when school is not in session—during the summer or before students enter school.

SUMMER SETBACKS. Students in poverty begin school about 6 months behind in reading skills compared to students from wealthier homes, but the difference between the groups grows to almost 3 years by sixth grade. This gap in reading skills between students in poverty and middle-class students has been increasing since the early 1970s. One explanation for this growing gap is that the children from poorer homes, and especially those whose first language is not English, lose ground over the summer. Even though both groups make comparable achievement gains during the school year, every summer vacation creates about a 3-month reading achievement gap between poor and advantaged children (Kim & Guryan, 2010; Kim & Quinn, 2013). One study suggested that the four summer vacations between second and sixth grade accounted for 80% of the achievement differences between poor and advantaged students (Allington & McGill-Frazen, 2003, 2008). This truly is a case of the rich getting richer. Wealthier children have greater access to books all the time, but especially over the summer.

Resistance culture Group values and beliefs about refusing to adopt the behaviors and attitudes of the majority culture.

GUIDELINES

Teaching Students Who Live in Poverty

Educate yourself about the effects of poverty on student learning.*Examples*

1. Read articles from good journals.
2. Seek diverse sources such as Eric Jensen's (2013), *Engaging Students with Poverty in Mind: Practical Strategies for Raising Achievement* and Paul Gorski's (2013) *Reaching and Teaching Students in Poverty: Strategies for Erasing the Opportunity Gap*.

Set and maintain high expectations for all students.*Examples*

1. Guard against feeling sorry for students, excusing poor work, and expecting less. Replace pity with empathy based on solid knowledge of your students.
2. Communicate to students that they can improve and succeed with good effort.
3. Engage higher-order thinking skills that validate students' intellectual capacities.
4. Provide constructive criticism because you believe your students can do quality work.
5. Add challenging subjects and AP classes.

Develop caring relationships with your students (see the 2015 Center for Promise report, "Don't Quit on Me.")*Examples*

1. Use inclusive language—"our class," "our projects," "our school," "our efforts."
2. Talk to students outside of class. Make a point to identify their interests and abilities.
3. Attend sports or other events in which your students participate.

4. Create a class Welcome Center for families (see Chapter 5).
5. Help a student connect with a mentor, tutor, and/or coach.

Build learning and self-regulation skills as part of the curriculum.*Examples*

1. Teach students how to organize work, focus attention, or seek appropriate help.
2. Include conflict management and social problem-solving skills in lessons.

Notice health problems.*Examples*

1. Notice who seems to be absent or tardy often.
2. Check to see whether some students struggle to hear the class discussions. Can they see from the back of the room?
3. Model healthy eating and physical activity.

Assess student knowledge; start where they are, but don't stay there (Milner, 2010).*Examples*

1. Use short, ungraded assessments that target the learning objectives for each unit.
2. Differentiate instruction (Chapter 14) based on results.

Sources: Jensen, E. (2013). *Engaging Students with Poverty in Mind: Practical Strategies for Raising Achievement*. Alexandria, VA: Association for Supervision and Curriculum Development.; Gorski, P. (2013). *Reaching and Teaching Students in Poverty: Strategies for Erasing the Opportunity Gap*. New York, NY: Teachers College Press; Center for Promise. (2015). *Don't Quit on Me: What Young People Who Left School Say About the Power of Relationships*. America's Promise Alliance: Washington, DC.

They read more, and the more children read, the better readers they become—volume of reading matters. The good news is that quality summer reading programs for low-income families and their children can be effective in helping students improve their reading skills (Kim & Quinn, 2013).

TRACKING: POOR TEACHING. A final explanation for the lower achievement of many students who live in low SES environments is that these students are more often placed in lower academic *tracks* and they are therefore actually taught differently (Oakes, 1990). If they are tracked into "low-ability," "general," "practical," or "vocational" classes, they may be taught to memorize and to learn more passively than their more advantaged peers. Middle-class students are more likely to be encouraged to think and be creative in their classes.

Even if they are not tracked, students from low-income families are more likely to attend schools with inadequate resources and less effective teachers (Evans, 2004). For example, in high-poverty schools, over 50% of math teachers and over 60% of science

teachers are inexperienced or teaching outside their subject area expertise; they were not trained for the subjects they are teaching (Jensen, 2009). When students with low SES receive a substandard education, this gives them inferior academic skills and limits their life chances, beginning with not preparing them for higher education (Anyon, 1980; Knapp & Woolverton, 2003). See the *Guidelines: Teaching Students Who Live in Poverty* for a few ideas about quality teaching for students who live in poverty.

MyLab Education **Self-Check 6.2**

ETHNICITY AND RACE IN TEACHING AND LEARNING

The United States truly is a diverse society. By around the year 2020, more than half of the school-age population will be African American, Asian, Latino/a, or from other ethnic groups (Chappell, 2015). Before we look at the research on ethnicity and race, let's clarify some terms.

Terms: Ethnicity and Race

Ethnicity usually refers to a group's shared common cultural characteristics such as history, homeland, language, traditions, or religion. We all have some ethnic heritage, whether our background is Italian, Ukrainian, Hmong, Chinese, Japanese, Navajo, Hawaiian, Puerto Rican, Cuban, Hungarian, German, African, or Irish—to name only a few. **Race** is defined as a socially constructed category of people who share certain physical characteristics (e.g., skin color or hair texture) that members of a society have considered important (Macionis, 2013). There are no biologically pure races. For any two humans chosen at random, an average of only .012% (about one-hundredth of 1%) of the alphabetic sequence of their genetic codes is different due to race (Myers, 2005).

Both ethnicity and race are therefore primarily social constructions that gain meaning within particular social or political contexts (Lee & Bean, 2010). At the individual level, they become part of our identity—how we understand ourselves and interact with others—when we are quite young. We examined ethnic identity development more closely in Chapter 3. At the group level, both ethnicity and race are involved with economic and political structures (Macionis, 2013). It is important to note that young people often make little or no distinction between their own race or ethnic identity—the two are inextricably intertwined. Researchers have therefore suggested that terms such as “racial-ethnic-cultural identity may be more appropriate when attempting to accurately represent the psychological experiences of youth of color forming an identity” (Umaña-Taylor et al., 2014). In this book I use the labels *ethnicity*, *race*, or *race/ethnicity* based on which label seems most appropriate to the findings being discussed.

Sociologists sometimes use the term **minority group** to label a group of people that receives unequal or discriminatory treatment. But this practice of referring to *people* as minorities because of their racial or ethnic heritage has been criticized because it is misleading and has negative historical connotations (Milner, 2010). For example, in certain places, such as Chicago or Mississippi, African Americans are in the numeric majority and European Americans are in the numeric minority. Unless otherwise specified, when I refer to *ethnic minority groups*, I do so using the entire U.S. population as a reference group. I often use the terms White, Black, and Latino instead of European American, African American, and Hispanic as these terms are more inclusive of students with diverse national origins (e.g., Canada, Haiti, or the Dominican Republic) and various immigration statuses. Teachers should be mindful of their own use of these terms when addressing their students' racial/ethnic heritage (for more information on terminology, see Christia Brown's 2017 book about students' perceptions of discrimination).

Ethnicity A cultural heritage shared by a group of people.

Race A socially constructed category based on appearances and ancestry.

Minority group A group of people who have been socially disadvantaged—not always a minority in actual numbers.

Ethnic and Racial Differences in School Achievement

A major concern in schools is that some ethnic groups consistently achieve below the average for all students (Matthews, Kizzie, Rowley, & Cortina, 2010; Uline & Johnson, 2005). This pattern of results tends to hold for all standardized achievement tests, but the gaps have been narrowing since about the 1980s and are less than the gaps seen between wealthy and poor students (Raudenbush, 2009; Reardon, 2011). For example, as you can see in Figure 6.3 on the National Assessment of Educational Progress in mathematics, the gap between scores of White and Black fourth-graders has narrowed from 34 points in 1996 to 24 points in 2015 (U.S. Department of Education, 2015). The gap between White and Hispanic fourth-graders has narrowed from 25 in 1996 to 18 in 2015 (National Center for Education Statistics, 2015). These gaps are larger in eighth grade (32-point gap for White and Black students; 22-point gap for White and Hispanic students).

Proponents of this notion of an “achievement gap” have been criticized for taking a narrow view, assuming that the scores of White, middle-class students are the norm that all other students must be compared to and measured by (Anyon, 2012). Multicultural scholar H. Richard Milner (2013, 2015) suggests that we think about other kinds of “gaps,” such as teacher education and quality gaps, challenging curriculum gaps, affordable housing and health care gaps, school integration and funding gaps, and quality childcare gaps, digital divide gaps, wealth and income gaps, employment gaps—all culminating in *opportunity gaps* for many students of color. Gloria Ladson-Billings (2006) described the *educational debt* that we owe students of color and students living in poverty based on decades of underinvestment and discrimination.

Opportunity gaps and educational debts lead to education completion gaps. Across the United States in 2014, about 87% of the White students graduated from high school, compared to 73% of African American students, 76% of Hispanic students, and 89% of Asian/Pacific Islanders (Kena et al., 2016). But again, these are averages across all the states. If we look state by state, we see some interesting differences. New Mexico had the lowest graduation rate (lower than 70%). Iowa and Nebraska had the highest graduation rates, at 90% or higher. But completion rates vary widely by ethnicity. Nevada graduated only 54% of Black high school students. In six states, the Black/White graduation rates differed by 20% or more. Graduate rates for Hispanic students vary from 63% in Minnesota to 86% in Texas (U.S. Department of Education, 2015). These differences probably have multiple causes. Some states have more families in poverty, more urban schools, less support for education, and other challenges.

Although consistent differences still exist among ethnic groups on tests of cognitive abilities, most researchers agree that the reasons for these differences are mainly the legacy of discrimination, the product of cultural mismatches and language differences, or a result of growing up in poverty. Because many students from ethnic groups are also economically disadvantaged, it is important to separate the effects of these two sets of influences on school achievement (Milner, 2015; Roberts, Mohammed, & Vaughn, 2010). For example, one study found that learning and self-regulation skills (e.g., attentiveness, persistence, organization, learning independence) explained the literacy development of African American boys from kindergarten to fifth grade, even after taking into account the effects of the boys’ SES, home environment, and problem behaviors (Matthews, Kizzie, Rowley, & Cortina, 2010). So, early development of these learning skills can help to close the opportunity gap, at least for African American boys, and probably for others.

Rather than focusing on achievement gaps, many educators have called for more research on the growth and successes of African American and Latino students. Berry (2005) studied two middle-school-aged African American boys who were successful in mathematics. In the lives of those students, Berry found support and high expectations from family and teachers; positive math experiences in preschool and elementary school; connections to church and athletic extracurricular activities; and positive identities as math students. One final theme characterized the successful African American boys—their families had prepared them to understand and deal with a legacy of inequality in schools, our next topic.

FIGURE 6.3

SCORES ON THE NATIONAL ASSESSMENT OF EDUCATIONAL PROGRESS IN FOURTH-GRADE MATHEMATICS

This figure compares the changes in the scores of White, African American, and Hispanic American fourth-graders between 1990 and 2013.

Note: Black includes African American, and Hispanic includes Latino. Race categories exclude Hispanic origin. Score gaps are calculated based on differences between unrounded average scores.

The Legacy of Inequality

When we considered explanations for why students with low SES have trouble in school, we listed the limited educational opportunities and low expectations/biases of teachers and fellow students. This also has been the experience of many students from ethnic minority groups. For example, in some areas of the South in 1924, Black students attended their own separate schools for only 6 months out of the year because they were expected to work in the fields the other 6 months. White students continued in their separate schools a full 9 months. The highest grade available for the Black students was eighth (Raudenbush, 2009).

PUT YOURSELF IN THEIR PLACE Legal segregation came to an end in 1954. Take a moment to imagine you were living back then and the child described here was your own. What would you do?

[In] the city of Topeka, Kansas, a minister walked hand in hand with his seven-year-old daughter to an elementary school four blocks from their home. Linda Brown wanted to enroll in the 2nd grade, but the school refused to admit her. Instead, public school officials required her to attend another school two miles away. This meant that she had to walk six blocks to a bus stop, where she sometimes waited half an hour for the bus. In bad weather, Linda Brown would be soaking wet by the time the bus came; one day she became so cold at the bus stop that she walked back home. Why, she asked her parents, could she not attend the school only four blocks away? (Macionis, 2003, p. 353) •

MyLab Education Video Example 6.2

This brief video documents several historical events surrounding desegregation and attempts by the federal government to end discrimination. Consider the achievement gaps that prevail in today's schools as a result of continued inequality.

Her parents' answer to this question, with the help of other concerned families, was to file a suit challenging the school policy. You know the outcome of the 1954 *Brown v. the Board of Education of Topeka* ruling. "Separate but equal" schools for Black children were declared inherently unequal.

Over 60 years later, years of research on the effects of desegregation have mostly shown that legally mandated integration is not a quick solution to the detrimental effects of centuries of racial inequality. In part because White students left desegregated schools and neighborhoods as the number of students of color increased, many urban schools today are more segregated than they were before the Supreme Court ordered busing and other desegregation measures (Orfield, Ee, Frankenburg, & Siegel-Hawley, 2016). For example, the schools in Los Angeles, Miami, Baltimore, Chicago, Dallas, Memphis, Houston, and Detroit have fewer than 11% non-Hispanic White students. In fact, two-thirds of the schools that African American and Latino students attend are quite segregated, with high concentrations of students living in poverty, so racial segregation becomes economic segregation as well (Ladson-Billings, 2004; Mickelson, Bottia, & Lambert, 2013; Raudenbush, 2009).

Parent and journalist Nikole Hannah-Jones (2016) described the tension she and her husband experienced when deciding whether to allow their daughter to attend a racially segregated, low-income public school in New York City. "Hadn't we worked hard . . . precisely so that she would not have to go to the types of schools that trapped so many black children?" This is the question many families face (see Hannah-Jones' 2015 broadcast on *This American Life*). Research suggests that the demographic composition of schools does indeed affect long-term outcomes. For example, economist Rucker Johnson (2015) found that Black adults who had attended more racially desegregated schools as children lived longer, were more likely to attend college and live in racially integrated neighborhoods, and were less likely to be poor, to suffer from chronic health problems, and to go to jail than were those adults who had attended racially segregated schools.

But even in "integrated" schools, too often students from ethnic or racial minority groups are reseggregated in low-ability tracks due to teachers' lower expectations about them (Tenenbaum & Ruck, 2007). Simply putting people in the same building does

not mean that they will come to respect each other or even that they will experience the same quality of education (Ladson-Billings, 2004; Mickelson et al., 2013). For more information on how to understand and reduce ethnic and racial disparities in education, look at the report by the American Psychological Association's Presidential Task Force on Educational Disparities (2012). One critical step in reducing disparities in educational outcomes is to acknowledge the role that prejudice and discrimination play in education.

WHAT IS PREJUDICE? The word *prejudice* is closely related to the word *prejudge*. **Prejudice** is a rigid and unfair generalization—a prejudgment—about an entire category of people. Prejudice is made up of *beliefs*, *emotions*, and tendencies toward particular *actions*. For example, you are prejudiced against people who are overweight if you think they are lazy (belief), feel disgusted (emotion), and refuse to date them (action) (Aboud et al., 2012; Myers, 2010). **Bias** refers to a prejudicial preference or action. Prejudice and bias can be positive or negative; that is, you can have positive as well as negative irrational beliefs about a group, but the terms usually refer to negative attitudes. Prejudice can be directed toward individuals of any particular group categorization, such as race, ethnicity, religion, politics, age, geographic location, language, sexual orientation, gender, or appearance.

Racial prejudice (racism) is pervasive, and it is not confined to one racial group. Some evidence suggests that blatant racism has decreased. For example, in 1970, more than 50% of Americans agreed that it was all right to keep members of minority groups out of their neighborhoods. By 1995, the number had dropped to about 10% (Myers, 2005). But there is more to racism than overt obvious racism. Subtle, below-the-surface racism remains, even though it may be outside of conscious awareness. Researchers have demonstrated this in numerous ways. For example, in response to police shootings of unarmed Black men, researchers created a videogame that showed a series of White or Black men holding either a gun or a non-weapon such as a flashlight or wallet. Participants in the research were told to “shoot” whenever the person in the videogame held a weapon. Race was not mentioned. Nevertheless, participants shot armed targets more quickly and more frequently when those targets were Black, rather than White, but decided not to shoot unarmed targets more quickly and more frequently when they were White (Greenwald, Oakes, & Hoffman, 2003). When the participants in another study were actual police officers, they were more likely to mistakenly shoot unarmed Black suspects compared with unarmed White suspects (Plant & Peruche, 2005).

You might think that police and teachers are quite different. Think again. Researchers have used similar techniques to show that teachers are more likely to expect less of students from ethnic minority groups and to disproportionately refer those from historically disadvantaged groups for special education or disciplinary interventions (van den Bergh, Denessen, Hornstra, Voeten, & Holland, 2010). In a society where few teachers would say they favor one group over another, how and why does this happen?

THE DEVELOPMENT OF PREJUDICE. Prejudice starts early. Results from studies around the world in areas with multiethnic populations show that prejudice based on ethnic group membership begins by age 4 or 5 (Aboud et al., 2012; Anzures et al., 2013). One popular belief is that young children are innocently colorblind and that they will not develop biases unless their parents teach them to be prejudiced. Although these beliefs are appealing, they are not supported by research. Even without direct coaching from their parents, many young children develop racial prejudice. Current explanations of the development of prejudice combine personal, social, and societal factors (Aboud et al., 2012; McKown, 2005).

One source of prejudice is the human tendency to divide the social world into two categories: us and them, or the in-group and the out-group. These divisions may be made on the basis of race, religion, gender, age, ethnicity, sexual orientation, or even athletic team membership. We tend to see members of the out-group as inferior to and different from us, but similar to each other—“they all look alike.” In fact, infants as

Connect and Extend to PRAXIS II®

Racial Bias (IV, B4)

Describe the possible effects of racial discrimination and bias on minority students. What can teachers and schools do to address the lingering effects of this discrimination?

Prejudice Prejudgment or irrational generalization about an entire category of people.

Bias A prejudicial preference or action.

young as 3 months show a preference for faces of their own race if they have had no experience with other races. By 9 months, infants have better recognition of own-race faces (Anzures et al., 2013).

Another source of prejudice is that adults who have more (more money, more social status, more prestige) may justify their privilege by assuming that they deserve to “have” because they are superior to the “have-nots.” This can lead to blaming the victims: People who live in poverty or women who are raped are seen as causing their problems by their behavior—“they got what they deserved.” Emotions play a part as well. When things go wrong, we look for someone or some whole group to blame. For example, after the tragic events of 9/11, some people vented their anger by attacking innocent Arab Americans (Myers, 2010).

But prejudice is more than a tendency to form in-groups, a self-justification, or an emotional reaction—it is also the product of a large storehouse of information and values that we gather throughout our lives. Children learn both explicitly and implicitly about traits and characteristics that are (or are not) valued by their families, peers, teachers, and the broader world around them. Think back to your analysis of commercials. Did you observe many women or people of color? For years, most of the models presented in books, films, television, and advertising were European Americans. People of different ethnic and racial backgrounds were seldom the “heroes” (Ward, 2004). This is changing. In 2002, the Oscar awards for best actress and best actor went to African Americans, but Denzel Washington won for his portrayal of a villain. In 2005, Jamie Foxx won an Oscar for his remarkable portrayal of Ray Charles—a hero. And of course, Barack Obama became president of the United States in 2008. Still, seeing historically oppressed groups acknowledged favorably by the media is not a given. A firestorm ensued after outstanding performances by several African American actors were snubbed at the 2016 Oscars. Similar negative portrayals in the media emerged throughout the 2016 U.S. presidential campaign, during which the Southern Poverty Law Center reported a surge in hate speech and racism (see <https://www.splcenter.org>).

STOP & THINK List three traits most characteristic of:

- College freshmen
- Politicians
- Athletes
- Buddhists
- Members of the National Rifle Association •

Prejudice is difficult to combat because it is based on categorizations that are part of our routine thinking processes. You will see in Chapter 8 that children develop schemas—organized bodies of knowledge—about objects, events, and actions. We have schemas that organize our knowledge about people we know and all our daily activities. We can also form schemas about groups of people. For the *Stop & Think* asking you to list the traits most characteristic of college freshmen, politicians, athletes, Buddhists, and members of the National Rifle Association, you probably could generate a list. That list would show that you have a stereotype—a schema—about each group. **Stereotypes** are simplified descriptions that you apply to every member of a group. These stereotypes actually are schemas that organize what you know, believe, and feel about the group. Stereotypes may incorporate prejudiced (rigid, unfair) beliefs about a group, but they don’t have to (Macionis, 2013).

As with any schema, we use our stereotypes to make sense of the world. Having a schema allows you to process information more quickly and efficiently. Once we have a schema, we tend to rely on it when we encounter new information. Although this is often useful, it can be dangerous when our categories are based on incomplete, limited, or biased information. We also over-rely on rigid, possibly biased, categories when we are under stress or have limited resources (Baumeister & Bargh, 2014). Teachers know these conditions well! Teachers, like police officers and all humans, can distort information to make it fit their schema better, especially if their stereotypes include prejudiced beliefs

Stereotype Schema that organizes knowledge or perceptions about a category.

about a group. We notice information that confirms or agrees with our stereotype—our schema—and miss or dismiss information that does not fit. Information that fits the stereotype is even processed more quickly (Kahneman, 2011).

FROM PREJUDICE TO DISCRIMINATION. Prejudice consists of rigid, irrational *beliefs* and *feelings* (usually negative) about an entire category of people. The third element of prejudice is a tendency to *act*, called discrimination. **Discrimination** is unequal treatment of particular categories of people. Clearly, many Americans face prejudice and discrimination in subtle or blatant ways every day. For example, Hispanics, African Americans, and Native Americans make up about 35% of the U.S. population, but in 2014, about 6.5% of the doctorates awarded went to Hispanic students, 6.4% to African Americans, and 0.2% to Native Americans. In contrast, 37% of the doctorates were awarded to non-residents of the United States (National Science Foundation, 2015). Black and Hispanic students begin to lose out in science and math as early as elementary school. They are chosen less often for gifted classes and acceleration or enrichment programs. They are more likely to be tracked into “basic skills” classes. As they progress through middle school, high school, and college, their paths take them farther and farther out of the pipeline that produces our scientists. If they do persist and become scientists or engineers, they, along with women, will still be paid less than White employees for the same work (National Science Foundation, 2015; Shen, 2016).

Although prejudice and discrimination come from many places—peers, media, social encounters outside of school—evidence suggests that perceiving discrimination from a teacher may be the most damaging for educational outcomes (Benner & Graham, 2013). As noted earlier, teachers are often unaware of their prejudices. Yet these prejudices can affect teachers’ expectations for their students and their interpretations of students’ behaviors. For example, researchers at Yale asked teachers to watch videos featuring racially diverse preschool children. Some teachers were primed to expect the students to show “challenging behaviors” and others were not. Teachers primed to look for misbehavior gazed longer at Black children—especially Black boys—than at White children, suggesting a form of implicit bias. Both Black and White teachers showed similar patterns (Gilliam, Maupin, Reyes, Accavitti, & Shic, 2016). This type of unconscious bias could be partly responsible for the disproportionate number of suspensions of Black students relative to their White peers (U.S. Department of Education, 2016). Another recent study found that non-Black high school teachers held lower expectations of Black students (particularly of boys) than did Black teachers (Gershenson, Holt, & Papageorge, 2016). As we will see, these biases can have serious effects (even if unintentional) on students’ educational attainment.

The families of racial and ethnic minority students often have to be vigilant about discrimination to protect their children. Teachers may unintentionally offend these families if they are not sensitive. Carol Orange (2005) described a teacher who sent home a holiday worksheet that featured an alphabetical list of all the students in the class. Three students’ names were not in the typed list, but were handwritten, out of order, and on the side of the sheet. Two of these students were Latino and one was African American. The mother of the African American student was very upset that her son was truly “marginalized” (written in the margins) on the list. These three students were added to the class (and hence, the list) later in the year, after the list was set up, but the teacher could have avoided this insult (unintended on her part) by redoing the list to give every student a place—a small but important symbol that she valued each one of them.

Developmental psychologist Christia Brown (2017) has shown that even young children have an awareness of prejudice and must be hypervigilant about discrimination. The good news is these learners also are highly attuned to whether they are welcomed and included by others at school. But being tuned in to and experiencing discrimination can make students feel less valued, overlooked, or even excluded, all of which make it difficult to stay motivated about school. Feeling like you must constantly monitor the environment for possible stereotypes and prejudice can undermine academic achievement—a concept referred to as stereotype threat.

Discrimination Treating or acting unfairly toward particular categories of people.

MyLab Education Video Example 6.3

A Native American who grew up on a reservation talks about the effect of being taught the majority culture's perspective. His ancestors occupied this land long before Columbus "discovered" America. Consider how the self-worth of Native Americans has been affected by discrimination. Examine comparable types of discrimination that affect other groups in our classrooms.

Stereotype Threat

Stereotype threat is an "apprehensiveness about confirming a stereotype" (Aronson, 2002, p. 282). The basic idea is that when individuals are in situations in which a stereotype applies, they bear an extra emotional and cognitive burden—the possibility of confirming the stereotype, either in the eyes of others or in their own eyes. So, when girls are asked to solve complicated mathematics problems or African Americans take the SATs, for example, they are at risk of confirming widely held stereotypes that girls are inferior to boys in mathematics or African Americans score lower on SATs. It is not necessary for the individual to believe the stereotype. All that matters is that the person is aware of the stereotype and cares about performing well enough to disprove its unflattering implications. The impact seems to be worse for adolescents who identify with the group threatened ("I am proud to be African American") and with the subject ("Science is really important to me!") (Appel & Kronberger, 2012; Aronson, Lustina, Good, Keough, Steele, & Brown, 1999; Huguet & Régner, 2007).

WHO IS AFFECTED BY STEREOTYPE THREAT? In a series of experiments, Joshua Aronson, Claude Steele, and their colleagues demonstrated that when African American or Latino college students are put in situations that induce stereotype threat, their performance suffers (Aronson & Steele, 2005; Okagaki, 2006; Schmader, Johns, & Forbes, 2008). For example, African American and White undergraduate subjects in an experiment at Stanford University were told that the test they were about to take would precisely measure their verbal ability. A similar group of subjects was told that the purpose of the test was to understand the psychology of verbal problem solving and not to assess individual ability. When the test was presented as diagnostic of verbal ability, the African American students solved about half as many problems as the White students. In the nonthreat situation, the two groups solved about the same number of problems.

Many people, not just women or students from minority groups, can be susceptible to stereotype threat. In other studies, stereotype threat depressed the performance of students from lower-SES backgrounds, elderly test takers, White male college students who were very strong in mathematics but were told that Asian students performed much better than White students on that particular test, and school-age children (Aronson, Lustina, et al., 1999; Hartley & Sutton, 2013). For example, Bonny Hartley and Robbie Sutton (2013) conducted three studies of stereotype threat in young students. In the first study they found that girls from age 4 and boys from age 7 believed that girls are better in school than boys and thought that adults believed that too. In the second study, a group of 7- to 8-year-old boys and girls took a test. The experimental group was told that girls do better on this test, but a control group was told that the researchers just wanted to "see how you do." Figure 6.4 shows the results. Boys in the stereotype condition did significantly worse, but girls' test performance was not affected. In a third study, when students in the experimental condition were told the researchers expected boys and girls to score the same on the test, the effects of stereotype threat disappeared.

Why and how does stereotype threat affect learning? Experiencing this threat: (1) prevents individuals from performing at their best on tests and assignments, (2) interferes with attention, working memory, and learning in the subject (e.g., math), and (3) decreases connections to and valuing of that subject (Appel & Kronberger, 2012; Huguet & Régner, 2007). Thus stereotype threat may be one cause, but not the sole cause, of the achievement gap between some ethnic groups (Nadler & Clark, 2011). Let's examine what the effects of stereotype threat look like in school.

SHORT-TERM EFFECTS: TEST PERFORMANCE. One review of the research on women, math, and stereotype threat concluded that very subtle clues that might activate anxiety, such as asking test takers to indicate their gender on an answer sheet before taking a math test, tend to lower math scores for women, especially when tests are difficult, the women are moderately identified with the math field, and being female is an important part of their identity. This makes sense because the individuals most vulnerable to stereotype threat are those who care the most and who are most deeply invested in high

Stereotype threat The extra emotional and cognitive burden that your performance in an academic situation might confirm a stereotype that others hold about you.

FIGURE 6.4

THE IMPACT OF STEREOTYPE THREAT ON STUDENT PERFORMANCE

When boys were told “girls do better than boys” on this test (stereotype threat), the boys’ performance was depressed, but when there was no stereotype threat, the boys and girls performed the same.

performance (Hartley & Sutton, 2013; Régner, Steele, Ambady, Thinus-Blanc, & Huguet, 2014). The differences are small on average—something like a female with average math ability scoring 450 instead of the expected average of 500 on an SAT- or GRE-type test. One study estimated that removing stereotype threat might mean that an additional 6% of women would earn a passing score on a high-stakes calculus test (Nguyen & Ryan, 2008; Wout, Dasco, Jackson, & Spencer, 2008).

Katherine Ryan and Allison Ryan (2005) developed a model to explain the links between stereotype threat and lower math performance for women and African Americans. When these students are in situations that evoke stereotype threats, such as high-pressure tests, they tend to adopt performance-avoidance goals, which means the students want to avoid looking dumb (more about these goals in Chapter 12). Students who set these self-protective goals don’t persist or use effective strategies. They tend to adopt self-handicapping strategies such as not trying or procrastinating—they just want to survive without looking too bad. But because they put off studying or didn’t try, they are anxious and unprepared during the test. Two other related explanations are that stereotype threat reduces working memory capacity—so students can’t hold as much in their minds (Okagaki, 2006)—and that it also decreases interest and engagement in the task. Why get absorbed in something that will make you look incompetent? (J. L. Smith, Sansone, & White, 2007; Thoman, Smith, Brown, Chase, & Lee, 2013).

LONG-TERM EFFECTS: DISIDENTIFICATION. Students who experience stereotype threat are less likely to feel a sense of belonging and connection in the context where the threat is “in the air.” When they feel disconnected, motivation and engagement suffer (Thoman et al., 2013). If students continue to adopt performance-avoidance goals, develop self-defeating strategies to avoid looking stupid, lose interest, lack a sense of belonging, and feel anxious in testing situations, they may withdraw, claim to not care, exert little effort, or even drop out of school. They psychologically disengage from

success and claim “math is for nerds” or “school is for losers.” Once students define academics as “uncool,” it is unlikely they will exert the effort needed for real learning. Some evidence indicates that Black male students are more likely than Black female students and White students to disidentify with academics—to separate their sense of self-esteem from their academic achievement (Cokley, 2002; Major & Schmader, 1998; C. Steele, 1992). This seems reasonable, given that identification with a particular subject (e.g., seeing yourself as a math person) leads to more devastating effects when you fear confirming a negative stereotype in that subject. For example, when African American children were faced with a “diagnostic” reading test, those who expressed a stronger identification with school experienced higher anxiety and more self-doubt than did students who had a lower identification with school (Wasserberg, 2014).

Other studies have questioned this disidentification connection, however. Historically, education has been valued among African American communities (Gorski, 2013; Milner, 2015; Walker, 1996). One study found that African American adolescents who had strong Afrocentric beliefs also had higher achievement goals and self-esteem than adolescents who identified with the larger White culture (Spencer, Noll, Stoltzfus, & Harpalani, 2001). Brown and Chu (2012) similarly found that Latino children who held positive feelings about their ethnic group performed better academically and were less likely to be adversely affected by discrimination from their teachers. Indeed, a strong connection to your ethnic group can serve as a buffer against the damaging effects of discrimination and stereotype threat (Nasir, Rowley, & Perez, 2015). How can teachers, parents, and students combat the adverse effects of stereotype threat and discrimination?

COMBATING STEREOTYPE THREAT AND DISCRIMINATION. One clear message for teachers is to help all students see academic achievement as part of their ethnic, racial, and gender identity. Teachers play an important role in this regard. For example, Mexican immigrant children in predominantly White elementary schools whose teachers valued diversity identified more positively with their ethnic group than did students whose teachers did not value diversity as much (Brown & Chu, 2012). Furthermore, these students whose teachers prized diversity perceived less discrimination than did their peers.

Teachers and parents should also ensure that students have a **growth mindset**, that is, they believe their learning and intelligence are fluid and can be changed. In one study, African American and White undergraduates were asked to write letters to middle school students who were “at risk,” to encourage them to persist in school. Some of the undergraduates were given evidence that intelligence is improvable and encouraged to communicate this information to their pen pals. Others were given information about multiple intelligences but not told that these multiple abilities can be improved. The middle school students were not real, but the process of writing persuasive letters about improving intelligence proved powerful. The African American college students—and the White students to a lesser extent—who were encouraged to believe that intelligence can be improved had higher grade-point averages and reported greater enjoyment of and engagement in school when contacted at the end of the next school quarter (Aronson, Fried, & Good, 2002). In another study, changing their beliefs about the improbability of intelligence led to higher year-end math achievement scores for middle school girls (C. Good, Aronson, & Inzlicht, 2003). So, having a growth mindset, believing that intelligence can be improved, might help inoculate students against stereotype threat.

Just reframing a threatening test as a “challenge” that “sharpens the mind” decreased the impact of stereotype threat for fourth- to sixth-grade African American students and for Princeton University students from high schools that rarely send students to Ivy League schools (Alter, Aronson, Darley, Rodriguez, & Ruble, 2009). Completing self-affirmation tasks in school such as writing about personal values also seems to minimize the effects of stereotype threat (Sherman et al., 2013).

Teachers must also consider their responsibility to care for students who are victims of discrimination and harassment both in school and in the broader society. During the 2016 presidential campaign, over two-thirds of teachers indicated that their students—primarily those who are immigrants, Muslims, African Americans, and other students

Growth mindset

A personally held belief that abilities are unstable, controllable, and improvable.

of color—expressed anxiety and fear about the election of Donald Trump (Costello, 2016). As one teacher noted, the tone of the election “emboldened [many students] to make bigoted and inflammatory statements about minorities, immigrants, the poor, etc.” (p. 10). Following the election, leaders of the American Educational Research Association urged educators “to take a stand against the violence, violent threats, and any act that is intended to restrict opportunity in whatever form, threaten the well-being of our students, or victimize those who contribute to our society” (Gadsden & Levine, 2016).

The fear of victimization, police brutality, or deportation creates conditions of extreme stress for some learners, and, as we have already seen, stress and anxiety make it difficult for students to learn. Although teachers are in a unique position to mitigate this stress, some choose not to engage with their students or feel uncertain about how best to do so. Others have used the election as an opportunity to teach about government and its role in protecting and respecting human rights. You will find some suggestions for making the classroom a welcoming space for all learners at the end of this chapter.

In Chapter 12, we will discuss test anxiety and how to overcome the negative effects of anxiety. Many of these strategies are also appropriate for helping students resist both stereotype threat and covert and overt forms of oppression.

MyLab Education Self-Check 6.3

GENDER IN TEACHING AND LEARNING

In this section, we examine the development of gender identity. We particularly focus on how men and women are socialized and the role of teachers in providing an equitable education for all students, regardless of their particular identities.

Sex and Gender

The word *gender* usually refers to traits and behaviors that a particular culture judges to be appropriate for boys and girls, men and women. In contrast, *sex* refers to biological differences (Brannon, 2002). An individual’s identity in terms of gender and sex is multifaceted. In this section, we examine the role of three important facets: gender identity, gender roles, and sexual orientation (Ruble, Martin, & Berenbaum, 2006). **Gender identity** is a person’s self-identification as a gendered individual. Although gender identity has historically been described in binary terms (i.e., male or female), it is better conceptualized along a continuum. This more inclusive view recognizes many forms of gender expression. **Gender roles** are those behaviors and characteristics that the culture stereotypically associates with a binary (male/female) view of gender. **Sexual orientation** refers to the type of people to whom you are sexually or emotionally attracted (Savin-Williams & Cohen, 2015). Sexual minority youth identify as or are attracted to others in nonheterosexual (e.g., gay, lesbian, bisexual) ways (Toomey & Russell, 2016). Relations among these three elements are complex. For example, a woman may identify herself as a female (gender identity) but behave in ways that are not consistent with the stereotypical gender role for girls (play football or wrestle) and may be attracted to both men and women (i.e., bisexual). Let’s look at some of these facets in further detail.

Gender Identity

Gender identity refers to a personal sense of being female, male, both, or neither (Brown & Stone, 2016). Erikson and many other earlier psychologists thought that identifying your gender was straightforward; you simply realized that you were male or female and acted accordingly. But today, we know that a person’s gender identity may be different from the sex assigned at birth. *Transgender* individuals often report feeling trapped in the wrong body; they experience themselves as female, but their biological sex is male, or vice versa (Lhamon & Gupta, 2016; Ruble et al., 2006). In a poignant self-disclosure,

Gender identity The sense of self as male or female as well as the beliefs one has about gender roles and attributes.

Gender roles The behaviors and characteristics that the culture stereotypically associates with bring male or female.

Sexual orientation The gender to whom a person is sexually or emotionally attracted.

one of my undergraduate students recently told our class that she spent her childhood knowing that she was really a boy, with the distinct feeling that “my insides don’t match my outsides.” Others might simply behave in *gender-expansive*, *gender nonconforming*, or *gender atypical* ways. A young boy may surround himself with girls, play with dolls, and dress as girls do. He might identify with most girls more than with most boys and might therefore resist a binary gender label.

Some children’s gender identity is formed early and remains relatively permanent. However, gender identity formation may take longer for others. Students who express themselves in gender atypical ways might be vulnerable to stigma, discrimination, or lower self-beliefs. For example, researchers in Holland asked seventh-grade students how gender typical they felt. Students who reported higher gender atypicality felt less confident in their academic capabilities than did gender-typical students (Vantieghem, Vermeersch, & Van Houtte, 2014). Teachers can play an important role in supporting students during their process of gender identity formation.

Gender Roles

Gender roles are expectations about how people should behave in gender conforming ways—in other words, in ways consistent with what is considered masculine or feminine. Gender roles vary by culture, time, and place. What was expected of women in the United States in the 1700s definitely has changed, even though women generally still are the primary caregivers and in charge of the home.

When and how do children develop their understanding of masculine and feminine gender roles? As early as age 2, children are aware of gender differences. They know whether they are a girl or a boy and that mommy is a girl and daddy is a boy. By age 3 or so, many begin to believe that their sex cannot be changed. Biology plays a part in gender-role development. Very early, hormones affect activity level and aggression, with boys tending to prefer active, rough, noisy play. Play styles lead young children to prefer same-sex play partners with similar styles, so by age 4, children spend three times as much play time with same-sex playmates as with opposite-sex playmates; by age 6, the ratio is 11 to 1 (Halim, Ruble, Tamis-LeMonda, & Shrout, 2013; Hines, 2004). Biology is not the whole story, however. The fact that boys tend to play with boys and girls with girls might lead to a gender-segregation cycle by which gender-role norms are defined and reinforced (Martin, Fabes, & Hanish, 2014).

Boys and girls may be treated differently, too. Researchers have found that boys are given more freedom to roam the neighborhood and are allowed to attempt potentially dangerous activities earlier, such as crossing the street alone. Thus, independence and initiative seem to be encouraged more in boys than in girls. In fact, parents, peers, and teachers may reward behaviors that seem gender appropriate—gentle kindness in girls and strong assertiveness in boys (Brannon, 2002; Brown, 2014).

And then there are the toys! Walk through most stores’ toy sections or order a child’s fast food meal, and see what is offered to girls and boys. Dolls and kitchen sets for girls and toy weapons for boys have been with us for decades. Then came aisles of princess paraphernalia for girls and battle video games for boys. Are consumers partly to blame? Adults often select gender-typed gifts for children, and fathers tend to discourage young sons from playing with “girl” toys (Brannon, 2002; Brown, 2014). When a large retailer announced recently that it would no longer segregate toys by gender, many parents were outraged. And let’s face it, gender socialization does not stop in childhood. I was recently helping a first-year student move into his co-ed dormitory on campus. His door was decorated with a card with his name alongside a hot-rod car; his female dorm-mates had princess tiara name cards on their doors. What are the consequences of such environmental messages about gender?

Through their interactions with family, peers, teachers, toys, and the environment in general, children begin to form **gender schemas**, or organized networks of knowledge about what it means to be male or female. Gender schemas help children make sense of the world and guide their behavior (see Figure 6.5). So a young girl whose schema for “girls” includes “girls play with dolls and not with trucks” or “girls can’t be scientists” will

Gender schemas

Organized cognitive structures that include gender-related information that influences how children think and behave.

FIGURE 6.5

GENDER SCHEMA THEORY

According to gender schema theory, children and adolescents use gender as an organizing theme to classify and understand their perceptions about the world.

pay attention to, remember, and interact more with dolls than trucks, and she may avoid science activities (Golombok et al., 2008; Leaper, 2002). Of course, these are averages, and individuals do not always fit the average. An individual girl might decide, for example, that the gender schema “trucks are for boys” doesn’t matter to her. She plays with the truck if it interests her (Liben & Bigler, 2002). By age 4, children have an initial sense of gender roles, and by 5 or so, they have developed a gender schema that describes what clothes, games, toys, behaviors, and careers are “right” for boys and girls—and these ideas can be quite rigid (Brannon, 2002; Halim et al., 2013).

Even in this era of great progress toward equal opportunity, a preschool girl is more likely to tell you she wants to become a nurse than to say she wants to be an engineer. After she had given a lecture on the dangers of sex stereotyping in schools, a colleague of mine brought her young daughter to her college class. The students asked the little girl, “What do you want to be when you grow up?” The child immediately replied, “A doctor,” and her professor/mother beamed with pride. Then the girl whispered to the students in the front row, “I really want to be a nurse, but my Mommy won’t let me.” Actually, this is a common reaction for young children. Preschoolers tend to have more stereotyped notions of sex roles than older children, and all ages seem to have more rigid and traditional ideas about male occupations than about what occupations women should pursue (Woolfolk & Perry, 2015).

Later, as children approach and enter puberty, they may become even more focused on behaving in “masculine” or “feminine” ways, as defined by their peer culture, social media, parents, or the environment. For example, in one study, children and early adolescents who were shown sexualized and nonsexualized images of girls rated the sexualized girls as more popular than the nonsexualized girls, but also viewed the sexualized girls as not as athletic, smart, and nice (Stone, Brown, & Jewell, 2015). The sexualized gender stereotype was more strongly endorsed by girls and by older students, suggesting that exposure to sexualized images in the media increases as children get older and may be especially important to girls as they form their schemas about gender.

Other research has shown that when parents (particularly mothers) see the usefulness and value of science, technology, engineering, and mathematics (STEM) fields, their children enroll in more STEM courses throughout high school (Rosek, Hyde, Svoboda, Hulleman, & Harackiewicz, 2015). Even small changes in the learning environment (e.g., when a computer science classroom contains stereotypical objects such as science fiction books versus plants) can invoke gender stereotypes that disadvantage some students. One study showed that just reading about a stereotypical computer science

classroom caused adolescent girls to feel less like taking the class for fear they would not belong (Master, Cheryan, & Meltzoff, 2016). The bottom line is that so many factors, from biology to cultural norms, play a role in gender-role development. Beware of either/or explanations.

Gender Bias in Curriculum Materials and Media

While I was proofreading this very page for a previous edition, riding cross-country on a train, the conductor stopped beside my seat. He said, “I’m sorry, dear, for interrupting your *homework*, but do you have a ticket?” I had to smile at his (I’m sure unintended) sexism. I doubt that he made the same comment to the man across the aisle who was writing on his legal pad. Like racial discrimination, messages of sexism and **gender biases** can be subtle, and they can and do appear in classrooms (see Brown & Stone, 2016; Leaper & Brown, 2014).

Unfortunately, schools often foster sexism in a number of ways. Publishers have established guidelines to prevent gender bias in educational materials, but it still makes sense to check them for stereotypes, particularly given the slow turnover of books that populate school library shelves. For example, even though children’s books now have an equal number of males and females as central characters, there still are more males in the titles and the illustrations, and the characters (especially the boys) continue to behave in stereotypic ways. Boys are more aggressive and argumentative, and girls are more expressive and affectionate. Girl characters sometimes cross gender roles to be more active, but boy characters seldom show “feminine” expressive traits (Brannon, 2002; Brown, 2014; Evans & Davies, 2000). Also, video learning packages, virtual worlds, social media sites, and online sources such as YouTube have not been carefully screened for gender, racial, ethnic, economic, religious, or age stereotypes and biases, and they can be sources of stereotyped messages (Henry, 2011). Digital teaching and testing materials and computer programs often feature boys more than girls and include other biases. One look at the body builds of males and females in video combat games shows what unreal and unhealthy body images they promote.

Another “text” that students read long before they arrive in your classroom is televised and online media. A content analysis of television commercials found that White male characters were more prominent than any other group (did you find that when you took the “commercial break” in the *Stop & Think* activity earlier?). Even when only the actor’s voice could be heard, men were 10 times more likely to narrate commercials. And the same pattern of men as the “voice of authority” on television occurred in the United Kingdom, Europe, Australia, and Asia. Women were more likely to be depicted as dependent on men and often were shown at home (Brannon, 2002). So, both before and after going to school, students are likely to encounter texts that overrepresent males. The documentary film *Miss Representation* (Siebel Newsom, 2011) offers numerous compelling (and rather shocking) examples of how mainstream media and culture depict girls and women in hypersexualized and underpowered positions (see <http://therepresentationproject.org> for more information, including an educator toolkit).

Gender Bias in Teaching

Quite a bit of research has studied teachers’ treatment of male and female students. You should know, however, that most of these studies have focused on White students, so the results reported in this section hold mostly for White male and female students.

Many studies describe what seem like biases favoring boys. One of the best-documented findings of the past 30 years is that teachers have more overall interactions with boys than with girls; however, this includes more negative interactions with boys but not more positive interactions (Jones & Dindia, 2004). This is true from preschool to college. Teachers ask more questions of males, give males more feedback (praise, criticism, and correction), and offer more specific and valuable comments to boys. Of course, these differences are not evenly distributed. Some boys, generally high-achieving White students, receive more than their share, whereas high-achieving

MyLab Education Video Example 6.4

In this video, 7-year-old Callie answers questions about subjects she likes and dislikes in school and math games she likes to play. As you listen to her answer the questions, consider the extent to which her answers do or do not follow stereotypical gender patterns.

Gender Bias (IV, B4)

There has been much debate in the news media over possible gender bias in schools. What can you as a teacher do to reduce or eliminate gender bias and its effects?

Gender biases Different views of males and females, often favoring one gender over the other.

White girls receive the least teacher attention. On average, teachers rate boys as more competent in mathematics than girls, unless girls are perceived as working harder, behaving better, and being more eager to learn than boys. Only then do teachers rate girls' math competence similarly to that of boys (Robinson-Cimpian, Lubinski, Ganley, & Copur-Gencturk, 2014).

Recent efforts have also examined how teachers' implicit beliefs and attitudes (think back to the iceberg metaphor presented earlier) might differentially affect girls and boys. For instance, some evidence has shown that girls pick up on the attitudes of their teachers. In one study, girls whose *teachers* had higher math anxiety scored lower on end-of-year math tests and were more likely to endorse the view that boys are better than girls in math (Beilock, Gunderson, Ramirez, & Levine, 2010). Teachers may not be aware of how their behaviors are influenced by their own attitudes, but through direct instruction, modeling, or differential interactions with boys and girls, they can have a powerful influence on both how students see themselves and how they perform (Gunderson, Ramirez, Levine, & Beilock, 2012).

Not all biases in school favor boys. In the past 10 years in North America, Western Europe, Australia, and some Asian countries, educators have raised questions about whether schools are serving boys well. This concern is fueled by data from many countries that seem to show underachievement in boys. In fact, the underachievement of boys in school has been called "one of the most pressing educational equality challenges of current times" (Hartley & Sutton, 2013, p. 1716). More dramatic accusations include that schools are trying to destroy "boys' culture" and force "feminine, frilly content" on boys.

One explanation for why boys struggle in school is that the expectations of schooling do not fit the way boys learn (Gurian & Stephens, 2005), particularly African American boys (Stinson, 2006). Another suggestion is that boys sabotage their own learning by resisting school expectations and rules to "display their masculinity and get respect" (Kleinfeld, 2005, p. B6). Some suggest that boys need smaller classes, more discussions, better discipline, mentoring programs, and more men in their schools—90% of elementary teachers are female (Svoboda, 2001). A current suggestion for making schools more effective for both boys and girls is single-sex classrooms. In 2008, the *New York Times Magazine* had a cover story about that topic (Weil, 2008), and in 2015 and 2016, *The Atlantic* reported on its "resurgence" (Anderson, 2015; Yap, 2016). During the past decade, many school districts across the United States have experimented with single-sex classrooms in core subjects such as English, science, and mathematics (Herron, 2013). Do gender-segregated approaches work? Read the upcoming *Point/Counterpoint* on the next page for the arguments.

Both proponents and critics of single-sex schools generally agree that good education is never one-size-fits-all. Teachers must realize that there are no boy- or girl-specific teaching strategies—good teaching is good teaching. Regrouping students by sex does not make teaching easier; in fact, it can make class management more difficult. It can also intensify gender stereotyping. The *Guidelines: Avoiding Gender Bias in Teaching* on page 274 provide additional ideas about ways to avoid gender bias for all students in your classes. Giving careful attention to each student's motivation and achievement may mean that different approaches are called for at different times. As William James (1899/2001) long ago reminded teachers: "One can draw no specific rules for all this. It depends on close observation in the particular case" (p. 55).

SEXUAL ORIENTATION. Sexual orientation is about feelings of attraction—"an internal mechanism that directs a person's sexuality to females, males, or both, perhaps to varying degrees" (Savin-Williams & Vrangalova, 2013, p. 59). Sexual orientation and gender identity are separate and distinct aspects of human development (Orr et al., 2015). For example, a person who identifies as female may be attracted to both men and women (i.e., a bisexual orientation). Common labels for sexual orientation include *gay*, *lesbian*, and *bisexual*. Another frequently used category is *questioning*, which refers to being unsure of one's sexual orientation (Robinson & Espelage, 2012). But sexual orientation labels, like identity labels, can be incomplete representations of how individuals refer to themselves, and some prefer no label at all. This makes it somewhat difficult

POINT/COUNTERPOINT: Should Girls and Boys Be Taught Differently?

Proponents say that students are better off learning some things with their same-gender counterparts. Critics say that gender-segregated classrooms change little for learners, and may reinforce stereotypes and even lead to greater gender disparities.

POINT ▶ Boys and girls have unique strengths and challenges and should be taught in different ways. Many educators paid attention when, in 2001, the No Child Left Behind (NCLB) Act began to allow public schools to offer same-sex classes, which led to the 2006 amendment to the Title XI regulation that removed the ban on single-sex public education. In the spirit of innovation, many schools took up the call and began catering instruction to the unique needs of boys and girls. After all, findings from the 2012 PISA test revealed that among 15-year-olds worldwide, boys were disproportionately overrepresented at the lowest and highest ends of achievement in math and reading, and girls generally reported lower self-confidence and higher anxiety in math than boys (OECD, 2015). It seemed logical to examine whether all students would benefit from gender-specific instruction (Bigler, Hayes, & Liben, 2014).

Since then, over 1,000 school districts across the United States have implemented some degree of single-sex education (Klein, Lee, McKinsey, & Archer, 2014). Some

organizations, such as the Gurian Institute (<http://www.gurianinstitute.com/>), have offered books and professional development workshops for schools focused on how best to educate each gender based on the core assumption that boys and girls have different learning “styles” (Gurian & Stevens, 2005). A staunch proponent of single-sex classrooms, Leonard Sax (2005) has suggested that these styles are rooted in fundamental biological differences between boys and girls that require different instructional approaches. Single-sex classrooms can help girls develop their own strengths and boost their self-confidence, interest, and achievement, particularly in STEM disciplines. Boys, on the other hand, can focus on strengthening their literacy skills and cooperativeness. Anecdotal findings reported by Gurian and others, primarily in popular media, have shown gains for both genders (e.g., Gurian, Stevens, & Daniels, 2009). Students and their families may have some choice in whether students attend a single-sex or a mixed-sex school, which could mean that such students are predisposed to respond well to the single-sex learning environment.

to assess the precise number of individuals of different sexual orientations within the population.

During adolescence, approximately 8% of boys and 6% of girls report engaging in some same-sex activity or feeling strong attractions to individuals of their own sex. Boys are more likely than girls to experiment with same-sex partners as adolescents, but young women are more likely to experiment later, often in college. Fewer adolescents actually have a homosexual or bisexual orientation; about 4% of adolescents identify as gay (young men who choose male partners), lesbian (young women who choose female partners), or bisexual (people who have partners of both sexes). This number increases to between 5% and 13% for adults (Savin-Williams, 2006). The manner in which individuals report their sexual orientation may affect these results. A student who wishes to engage in same-sex behaviors may not identify as gay, nor will he necessarily disclose his attractions to others (Savin-Williams & Cohen, 2015).

Quite a few identity development models have included a description of how individuals come to understand their sexual orientation if they are not heterosexual. Generally, the models include the following or similar stages (Savin-Williams & Cohen, 2015).

- *Feeling different*—Beginning around age 6, the child may be less interested in the activities of other children who are the same sex. Some children may find this difference troubling and fear being “found out.” Others do not experience these anxieties.
- *Feeling confused*—In adolescence, as they feel attractions for peers of the same sex, students may be confused, upset, lonely, and unsure of what to do. They may lack role models and may try to change themselves by becoming involved in activities and dating patterns that fit heterosexual stereotypes.

Girls and boys are more similar than different and should be taught together. Researchers who have looked critically at data used to support gender-segregated educational approaches have argued that these approaches come up short of fulfilling their promise of promoting gender equity in learning and psychological well-being. In their 2011 article, “The Pseudoscience of Single-Sex Schooling,” Diane Halpern and her colleagues noted that research studies on same-sex education have been “deeply misguided, and often justified by weak, cherry-picked, or misconstrued scientific claims rather than by valid scientific evidence” (p. 1706). For example, when researchers take into account students’ initial performance levels, many students’ achievement gains in single-sex classrooms disappear. These scholars argue that studies of single-sex schooling have lacked the statistical rigor of randomized assignment, and therefore findings could be due to sampling or researcher bias. In fact, Halpern and colleagues claim that separating boys and girls actually *worsens* outcomes by making gender differences (and therefore, stereotypes) more noticeable. They point to research showing that when any group of humans is set apart from another (based on gender, eye color, or even t-shirt color), people develop intergroup biases. Single-sex education, they argue, minimizes the very opportunities needed for gender equity—namely, teaching boys and girls to work alongside each other. “Positive and cooperative interaction with members of other groups is an effective method for improving intergroup relationships” (p. 1707).

But what about the evidence of biological differences between men and women? Are men really from Mars and women

from Venus? Hyde (2005) conducted a *meta meta-analysis* (i.e., a review of 46 meta-analyses) summarizing hundreds of studies on sex differences in a range of human behaviors. Her findings provided evidence for what she called the “gender similarities hypothesis.” With some important exceptions, men and women are highly similar on numerous psychological and performance metrics. The magnitude of these differences fluctuates across the lifespan and in different contexts, which can lead researchers to overestimate the size and stability of sex differences. For example, much of the evidence on sex differences has come from studies with adults who have had years of socialization; these sex differences are not necessarily present in children. Maybe boys and girls are from the same planet after all ... and should therefore be educated in similar ways.

Beware of Either/Or So do single-sex schools or classrooms improve learning? The answer is, “It depends.” A recent meta-analysis offers the most comprehensive answer to date, addressing some of the methodological problems identified by Halpern and her colleagues. Pahlke, Hyde, and Allison (2014) examined results from 184 studies involving 1.6 million students in Grades K–12 from 21 countries. They looked at whether students learning in single-sex schools versus those learning in coeducational schools displayed different performances and attitudes. To account for variable quality in research designs, the researchers ran separate analyses for studies that used random assignment from those that did not. Among studies that randomly assigned students to single-sex classrooms, only trivial differences emerged between students in the two settings. Both girls and boys performed marginally better in single-sex schools, but girls attending coeducational schools had higher educational aspirations than did girls attending same-sex schools.

- **Acceptance**—As adolescents or young adults, many individuals develop a sexual orientation and identify themselves as gay, lesbian, or bisexual. They may or may not make their sexual orientation public but might share the information with a few friends.

The problem with phase models of identity development is that the identity achieved is assumed to be final. Actually, newer models emphasize that sexual orientation can be flexible, complex, and multifaceted; it can change over a person’s lifetime. For example, people may have dated or married opposite-sex partners at one point in their lives but have same-sex attractions or partners later in their lives, or vice versa (Garnets, 2002).

Discrimination Based on Gender Expression and Sexual Orientation

Children and adolescents who express their gender or sexual orientation in nonconforming ways (that is, whose expressions are not typical of others their age) are more likely than their classmates to face discrimination by peers and adults (Brown, 2017; Brown & Stone, 2016). For example, a boy whose preferences or behaviors differ from the norms of masculinity is often teased, subject to homophobic slurs, stigmatized as being too feminine, or worse—physically assaulted. This is an affront to both boys and girls. Youth who identify as lesbian, gay, transgender, or bisexual (often referred to under the more inclusive term, *sexual minority youth*) are more likely to be victims of aggression at school, according to a recent meta-analysis (Toomey & Russell, 2016). National survey data have shown this, too. The 2011 National School Climate Survey asked adolescents to report their experiences in the past year. Among sexual minority youth who took the

GUIDELINES

Avoiding Gender Bias in Teaching

Check to see if textbooks and other media you are using present an honest view of the options open to men, women, and to gender nonconforming individuals.

Examples

1. Identify whether both men and women are portrayed in traditional and nontraditional roles at work, at leisure, and at home.
2. Discuss your analyses with students, and ask them to help you find sex-role biases in other materials—magazine advertising, TV programs, and news reporting, for example.

Watch for any unintended biases in your own classroom practices.

Examples

1. Monitor whether you group students by gender for certain activities. Consider how gendered groups might feel to students who do not prefer to identify themselves as boys or girls. Is the grouping appropriate?
2. Monitor whether you call on one sex or the other for certain answers—boys for math and girls for poetry, for example. Consider the quality of your feedback to students.
3. Monitor your metaphors. Don't ask students to "tackle the problem."

Look for ways in which your school may be limiting the options open to male or female students.

Examples

1. Find out what advice guidance counselors give to students in course and career decisions.
2. Look into whether there is a good sports program for both girls and boys.

3. See if girls are encouraged to take AP courses in science and mathematics and if boys are encouraged in English and foreign language classes.

Use gender-free language as much as possible.

Examples

1. Make sure you use inclusive terms (e.g., speaking of "law-enforcement officer" and "mail carrier" instead of "policeman" and "mailman").
2. Be sure you name a committee "head" instead of a "chairman."

Provide counter-stereotypical gender role models.

Examples

1. Assign articles in professional journals written by female research scientists or mathematicians.
2. Have recent female graduates who are majoring in science, math, engineering, or other technical fields come to class to talk about college.
3. Create electronic mentoring programs for both male and female students to connect them with adults working in areas of interest to the students.

Make sure all students have a chance to do complex, technical work.

Examples

1. Experiment with same-sex lab groups so girls do not always end up as the secretaries, boys as the technicians.
2. Rotate jobs in groups or randomly assign responsibilities.

What if you witness gender bias as a student teacher? For ideas see TeachingTolerance.org and search for "classroom resources."

survey, over 85% had heard the word "gay" being used in a derogatory manner, 70% had heard other homophobic comments used frequently at school, 82% had been victims of verbal harassment or threats, 55% had experienced some form of cyberbullying, and 38% were physically harassed or assaulted (Kosciw, Greytak, Bartkiewicz, Boesen, & Palmer, 2012). Almost all reported feeling distressed over these incidents, and half said they did not feel safe at school because of their sexual orientation and/or gender expression. These stressors can lead to lower academic performance among sexual minority youth (Poteat, Scheer, & Mereish, 2014).

The stress associated with such victimization is one reason why sexual minority students are at greater risk than their heterosexual peers for missing school and for attempting suicide (Robinson & Espelage, 2012). Transgender students are particularly susceptible to increased stress. Fortunately, educational programs and activities that are run by schools receiving U.S. federal assistance must abide by Title IX of the Education Amendments of 1972. Title IX protects the educational rights of all students and ensures them a safe and nondiscriminatory environment, regardless of their gender

TABLE 6.2 • Reaching Out to Help Students of Diverse Sexual Orientations

These ideas come from the Attic Speakers Bureau, a program of The Attic Youth Center, where trained peer educators reach out to youth and youth-service providers in schools, organizations, and health care facilities.

REACHING OUT
If a lesbian, gay, bisexual, or transgender youth or a youth questioning his or her own sexual orientation should come to you directly for assistance, remember the following simple, 5-point plan: LISTEN It seems obvious, but the best thing that you can do in the beginning is allow that individual to vent and express what is going on in his or her life. AFFIRM Tell them, “You are not alone.” This is crucial. A lot of LGBTQ youth feel isolated and lack peers with whom they can discuss issues around sexual orientation. Letting them know that there are others dealing with the same issues is invaluable. This statement is also important because it does not involve a judgment call on your part. REFER You do not have to be the expert. A referral to someone who is trained to deal with these issues is a gift you are giving to that student, not a dismissal of responsibility. ADDRESS Deal with harassers—do not overlook issues of verbal or physical harassment around sexual orientation. It is important to create and maintain an environment where all youth feel comfortable and welcome. FOLLOW-UP Be sure to check in with the individual to see if the situation has improved and if there is anything further you may be able to do. There are also some things that you as an individual can do to better serve 1/g/b/t/q youth and youth dealing with issues around sexual orientation: • Work on your own sense of comfort around issues of sexual orientation and sexuality. • Get training on how to present information on sexual orientation effectively. • Dispel myths around sexual orientation by knowing facts and sharing that information. • Work on setting aside your own personal biases to better serve students dealing with issues around sexual orientation and sexuality.

identity (Lhamon & Gupta, 2016). However, some states are currently challenging the interpretation of Title IX, and the U.S. Supreme Court will likely rule on this in the near future.

How can teachers create a safe learning environment for all students, regardless of their gender identity? A teacher’s ultimate goal, as one superintendent observed, should be to determine what a child needs “to feel safe, included, and supported” (Orr et al., 2015, p. ii). We talk about bullying and teachers’ roles in handling all types of bullying in Chapter 13. For now, let’s consider what you can do if students come to you with concerns about gender identity or sexual orientation. Even though parents and teachers are seldom the first people to hear about an adolescent’s gender identity concerns, you can be prepared. If a student does seek your counsel, Table 6.2 provides some ideas for reaching out and creating a safe environment for sexual minority youth. In addition, you may find it helpful to consult the *2016 Safe Space Kit: A Guide to Supporting Lesbian, Gay, Bisexual, and Transgender Student in Your School*, published by GLSEN and *Schools in Transition: A Guide for Supporting Transgender Students in K–12 Schools* (Orr et al., 2015). Both resources are readily available online. By simply offering a nonjudgmental presence, teachers can help sexual minority youth to develop a more positive and healthy identity (Riggle & Rostosky, 2012).

We have dealt with a wide range of differences in this chapter. How can teachers provide an appropriate education for all of their students? We turn now to this question.

Connect and Extend to PRAXIS II®

Multicultural Education (III, B)

Know the major dimensions of multicultural education. Describe how these dimensions influence each other.

CREATING CULTURALLY COMPATIBLE CLASSROOMS

Picture a tenth-grade class in urban Philadelphia, a first-grade class in rural Kentucky, and an eighth-grade class in El Paso. Now picture the classrooms you see on television and those where you were educated. Classrooms are the daily gathering places for a unique blend of individuals who are poor and rich and everything in between, who hail from widely varying cultural heritages, who express their gender and sexuality in stereotypical and nonstereotypical ways, and who display a rich tapestry of difference in other important aspects of life, such as religion, family composition, political affiliation, and (dis)ability. How can teachers, who begin their work from their own unique cultural locations, create classrooms that can hold, protect, and even embrace cultural diversity?

Some educators have noted that creating culturally compatible classrooms is at the foundation of providing a **multicultural education**, defined as

[a] process of comprehensive school reform and basic education for all students. It challenges and rejects racism and other forms of discrimination in schools and society and accepts and affirms the pluralism (ethnic, racial, linguistic, religious, economic, and gender, among others) that students, their communities, and their teachers reflect. (Nieto & Bode, 2012, p. 42)

James Banks (2014) suggests that multicultural education has five dimensions: *content integration*, *the knowledge construction process*, *prejudice reduction*, *an empowering school culture and social structure*, and *an equity pedagogy*, as shown in Figure 6.6. Many people are familiar only with the dimension of *content integration*, or using examples and content from a variety of cultures when teaching a subject. And because they believe that

FIGURE 6.6

BANKS'S DIMENSIONS OF MULTICULTURAL EDUCATION

Multicultural education is more than a change in curriculum. To make education appropriate for all students, we must consider other dimensions as well. The way the athletics and counseling programs are structured, the teaching method used, lessons about prejudice, perspectives on knowledge—these and many more elements contribute to true multicultural education.

Multicultural education Education that promotes equity in the schooling of all students.

Source: From James A. Banks (2014), *An Introduction to Multicultural Education* (5th edition). Boston, MA: Pearson. Reprinted with permission.

multicultural education is simply a change in content, some teachers assume that it is irrelevant for subjects such as science and mathematics. But if you consider the other four dimensions—helping students understand how knowledge is constructed, reducing prejudice, creating social structures in schools that support learning and development for all students, and using equity pedagogy or teaching methods that reach all students—then you will see that this view of multicultural education is relevant to all subjects and all students.

An examination of the alternative approaches to multicultural education is beyond the scope of an educational psychology text, but be aware that there is no general agreement about the “best” approach. Nevertheless, many educators have suggested that a *culturally relevant* pedagogical approach is beneficial in all classrooms.

Culturally Relevant Pedagogy

Several researchers have focused on teachers who are especially successful with students of color and students in poverty (Delpit, 1995; Edmin, 2016; Milner, 2015; Siddle Walker, 2001). The work of Gloria Ladson-Billings (1990, 1992, 1994, 1995) is a good example. For 3 years, she studied excellent teachers in a California school district that served an African American community. To select the teachers, she asked parents and principals for nominations. Parents nominated teachers who respected them, created enthusiasm for learning in their children, and understood their children’s need to operate successfully in two different worlds—the home community and the White world beyond. Principals nominated teachers who had few discipline referrals, high attendance rates, and students with high standardized test scores. Ladson-Billings was able to examine in depth 8 of the 9 teachers who were nominated by *both* parents and principals.

Based on her research, Ladson-Billings developed a conception of teaching excellence. She uses the term **culturally relevant pedagogy** to describe teaching that rests on three propositions.

1. *Students must experience academic success.* “Despite the current social inequities and hostile classroom environments, students must develop their academic skills. The ways those skills are developed may vary, but all students need literacy, numeracy, technological, social, and political skills in order to be active participants in a democracy” (Ladson-Billings, 1995, p. 160).
2. *Students must develop/maintain their cultural competence.* As they become more academically skilled, students still retain their cultural competence. “Culturally relevant teachers utilize students’ culture as a vehicle for learning” (Ladson-Billings, 1995, p. 161). For example, one teacher used rap music to teach about literal and figurative meaning, rhyme, alliteration, and onomatopoeia in poetry. Another brought in a community expert known for her sweet potato pies. Follow-up lessons included investigations of George Washington Carver’s sweet potato research, numerical analyses of taste tests, marketing plans for selling pies, and research on the educational preparation needed to become a chef.
3. *Students must develop a critical consciousness to challenge the status quo.* In addition to developing academic skills while retaining cultural competence, excellent teachers help students “develop a broader sociopolitical consciousness that allows them to critique the social norms, values, mores, and institutions that produce and maintain social inequities” (Ladson-Billings, 1995, p. 162). For example, in one school, students were upset that their textbooks were out of date. They mobilized to investigate the funding formulas that allowed middle-class students to have newer books, wrote letters to the newspaper editor to challenge these inequities, and updated their texts with current information from other sources.

Ladson-Billings (1995) noted that many people have said her three principles “are just good teaching.” She agrees that she is describing good teaching, but questions “why so little of it seems to be occurring in classrooms populated by African American students” (p. 159).

Lisa Delpit (2003) describes three steps for teaching students that are consistent with culturally relevant pedagogy: (1) Teachers must be convinced of the inherent intellectual capability, humanity, and spiritual character of their students—they must believe

Culturally relevant pedagogy Excellent teaching for students of color that includes academic success, developing/maintaining cultural competence, and developing a critical consciousness to challenge the status quo.

in the children. She has provided many examples from schools around the United States where ethnically diverse students from low-income families are reading well above grade level and doing advanced math (Delpit, 2012). When scores are low, the fault is not in the students but in their education. (2) Teachers must fight the foolishness asserting that high test scores or scripted lessons are evidence of good learning and good teaching. Successful instruction is “constant, rigorous, integrated across disciplines, connected to students’ lived cultures, connected to their intellectual legacies, engaging, and designed for critical thinking and problem solving that is useful beyond the classroom” (Delpit, 2003, p. 18). (3) Teachers must learn who their students are and what legacies they bring. Then, students can explore their own intellectual legacies and understand the important reasons for academic, social, physical, and moral excellence—not just to “get a job” but also “for our community, for your ancestors, for your descendants” (p. 19).

Michael Pressley and his colleagues (2004) did a case study of a very successful K–12 school for African American students. The characteristics of effective teaching at this school are shown in Table 6.3. How might they be applied to learners in other settings?

TABLE 6.3 • Research-Based Characteristics of Schools and Teachers Associated with Academic Achievement for African American Students

CHARACTERISTICS OF SCHOOLS	CHARACTERISTICS OF EFFECTIVE TEACHING	OTHER CHARACTERISTICS
Strong administrative leadership	Dedicated teachers who are accountable to produce results	Significant total academic time: A very long, functional school day/week, including before-school-hours to after-school-hours interactions and tutoring, good use of almost every minute of every class hour, and summer school for students who need it
Frequent evaluation of student progress	Significant teacher scaffolding, encouraging student self-regulation	Students who help one another with academics
Emphasis on academics	Curriculum and instruction emphasizing understanding	Strong family–school connections
Safe and orderly environment	Mentoring, especially with regard to college admissions	Donors and visibly supportive, successful alumni
High expectations for student achievement including selective recruitment/retention of students, with the school weeding out students who are not using the opportunity well in favor of students who will (i.e., weeding out misbehaving students, students not meeting academic standards)	Intentional, massive, and frequent attempts to motivate students, including use of the following mechanisms: Positive expectations Visible care by teachers and administrators Praise of specific accomplishments Generally positive atmosphere, encouragement of effort attributions Cooperative learning experiences Tangible rewards for achievements	Motivational mechanisms not often encountered in schools: Extreme community celebrations of academic achievements Encouragement for each student to envision a possible self as college graduate and successful professional Discouragement of envisioning negative future outcomes Development of informed pride in African American heritage and life
Excellent classroom management in most classrooms, resulting in a high proportion of academic time on task	Teachers who provide strong instructional supports for academic achievement (e.g., study guides, test expectations made apparent, informative, feedback on homework and before exams)	Many extracurricular and curricular-enrichment activities—almost all academically oriented or intended to increase commitment to academic pursuits
		An attractive school building loaded with resources to support academic pursuits

Source: Based on Pressley, M., Raphael, L., Gallagher, J. D., & DiBella, J. (2004). Providence St. Mel School: How a School That Works for African American Students Works. *Journal of Educational Psychology*, 96(2), pp. 234–235.

In the past, discussions about teaching low-income students and those from racial, ethnic, or linguistic minority groups have focused on remediating problems or overcoming perceived deficits. But thinking today emphasizes teaching to the strengths of these students. Beth Doll and her colleagues (2005) drew from research in education and psychology to uncover best practices for children in poverty and children with disabilities. They identified two strands that capitalize on student strengths and bind students to their classroom community: self-agency and connected relationships.

SELF-AGENCY STRAND.

- *Academic self-efficacy*, a belief in one's own ability to learn, is one of the most consistent predictors of academic achievement. As you will see in Chapter 11, self-efficacy emerges when students tackle challenging, meaningful tasks with the support needed to be successful and observe other students doing the same thing. Accurate and encouraging feedback from teachers also helps. This requires that teachers notice "the pain in children's eyes when they have internalized the societal beliefs that they are dumb, unmotivated, and dispensable" (Delpit, 2012, p. xx). Teachers can support students' self-efficacy by challenging societal messages that depict being Black and poor as "bad" and being White and wealthy as "good."
- *Behavioral self-control*, or student self-regulation, is essential for a safe and orderly learning environment. Chapters 7, 11, and 13 will give you ideas for helping students develop self-control.
- *Academic self-determination*, which includes making choices, setting goals, and following through, is the third element in the self-agency strand. As you will see in Chapter 12, students who are self-determined feel competent, autonomous, and connected to others, all of which can be facilitated by a caring teacher. Such students are more intrinsically motivated and committed to learning.

RELATIONSHIP STRAND.

- *Caring teacher–student relationships* are consistently associated with better school performance, especially for students who face serious challenges. You saw the power of caring teachers in Chapters 1 and 3, and you will continue to see the value of these relationships throughout this text.
- *Effective peer relations*, as you saw in Chapter 3, also are critical in connecting students to school.
- *Effective home–school relationships* are the final element in building a caring, connected network for students. In the School Development program, James Comer has found that when parents stay involved, their children's grades and test scores improve (Comer, Haynes, & Joyner, 1996).

Diversity in Learning

How might classrooms be organized to reflect the diverse ways in which students learn? Let's look at four ways that teachers can honor the cultural differences present in their classes that might affect student learning: social organization, cultural values and learning preferences, sociolinguistics, and cultural discontinuity. These were first introduced by Roland Tharp (1989) and offer useful suggestions for teachers.

SOCIAL ORGANIZATION. Social structure or organization refers to the ways people interact to accomplish a particular goal. For example, the social organization of Hawaiian society depends heavily on collaboration and cooperation. Children play together in groups of friends and siblings, with older children often caring for the younger ones. When cooperative work groups of four or five boys and girls were established in Hawaiian classrooms, student learning and participation improved (Okagaki, 2001, 2006). The teacher worked intensively with one group while the children in the remaining groups helped each other. But when the same structure was tried in a Navajo classroom, students would not work together. These children are socialized to be more solitary and not to play with children of the opposite sex. By setting up same-sex working groups of

only two or three Navajo students, teachers encouraged them to help each other. Providing choices and variety in grouping structures creates greater flexibility in the social organization of the classroom.

CULTURAL VALUES AND LEARNING PREFERENCES. As noted throughout this chapter, all learners (and teachers) have distinct values and preferences related to their diverse cultural backgrounds. For example, research has shown that some Hispanic American students are more oriented toward family and group loyalty. This may mean that these students prefer cooperative activities and dislike being made to compete with fellow students (Garcia, 1992; Vasquez, 1990). It may also mean that some students will behave in ways that reflect certain Latino values, such as these four identified by Dingfelder (2005):

Familismo: Tightly knit families. Discussing family problems or business may be seen as disloyal.

Simpatia: Value of interpersonal harmony. Assertively voicing personal opinions or arguing may be seen as inappropriate.

Respeto: Respect for people in authority, for example, teachers and government officials.

Personalismo: Valuing of close interpersonal relationships; discomfort with distant, cold, professional relationships.

The learning styles of African Americans may be inconsistent with teaching approaches in most schools. Some of the characteristics of this learning style are a visual/global approach rather than a verbal/analytic approach; a preference for reasoning by inference rather than by formal logic; a focus on people and relationships; a preference for energetic involvement in several activities simultaneously rather than routine, step-by-step learning; a tendency to approximate numbers, space, and time; and a greater dependence on nonverbal communication. Students of color who identify with their traditional cultures tend to respond better to open-ended questions with more than one answer, as opposed to single, right-answer questions. Questions that focus on meaning or the “big picture” may be more productive than questions that focus on details (Bennett, 2011; Gay, 2000; Sheets, 2005).

Native Americans appear to value humility and harmony more than competition. Many Native American students have a more global, visual style of learning. For example, Navajo students were shown to prefer hearing a story all the way through to the end before discussing parts of the story. Teachers who stop reading to ask comprehension questions seem odd to these students and interrupt their learning process (Tharp, 1989). Also, these students sometimes show strong preferences for learning privately, through trial and error, rather than having their mistakes made public (Morgan, 2009).

But, as you saw earlier, there are dangers in stereotyping any group, especially in terms of their cultural values or learning preferences. We should revisit some cautions here.

CAUTIONS (AGAIN) ABOUT LEARNING STYLES/PREFERENCES RESEARCH. In considering the research on cultural values and learning preferences, you should keep two points in mind. First, the validity of some of the learning styles research has been strongly questioned, as you saw in Chapter 4. Second, there is a heated debate today about whether identifying group differences in learning styles and preferences is a dangerous, racist (and/or sexist) exercise. In our society, we are quick to move from the notion of “difference” to the idea of “deficits” and stereotypes (Christopher, Wendt, Marecek, & Goodman, 2014). The latter view assumes that White, middle-class culture is “normal” and valuable (McIntosh, 1989, 2009; Paris, 2012).

The information about cultural learning style differences has been included here because I believe that, used sensibly, this information might help you better understand some of your students. But it is dangerous and incorrect to assume that every individual in a group shares the same learning style (Sheets, 2005; Tyler et al., 2008). The best advice for teachers is to be sensitive to individual differences in all your students and to make available alternative paths to learning. Never prejudge how a student will learn best based on assumptions about the student’s ethnicity, race, or gender. Get to know the individual.

SOCIOLINGUISTICS. Sociolinguistics is the study of “the courtesies and conventions of conversation across cultures” (Tharp, 1989, p. 351). The classroom is a special setting for communicating; it has its own set of rules for when, how, to whom, about what subject, and in what manner to use language. To be successful, students must know these communication rules; that is, they must understand the **pragmatics** of the classroom—when, where, and how to communicate. This is not such an easy task. As class activities change, rules change. Sometimes you have to raise your hand (during the teacher’s presentation), but sometimes you don’t (during story time on the rug or during an experiment in the lab). Sometimes it is good to ask a question (during discussion), but other times it isn’t so good (when the teacher is reprimanding you). These differing activity rules are called **participation structures**, and they define appropriate participation for each class activity. Most classrooms have many different participation structures. To be competent communicators in the classroom, students sometimes have to read very subtle, nonverbal cues telling them which participation structures are currently in effect. For example, when the teacher moves to the white board, students should look up and be ready for instructions.

Some children are simply better than others at reading classroom situations because the participation structures of the school match the structures they have learned at home (Tyler et al., 2008). The communication rules for most school situations are similar to those in middle-class homes, so children from these homes often appear to be more competent communicators. They know the unwritten rules. It seems that even students who speak the same language as their teachers may still have trouble communicating and so have trouble learning school subjects. What can teachers do? You can begin by making communication rules for activities clear and explicit. Do not assume students know what to do. Use cues to signal students when changes occur. Explain and demonstrate desired behavior. I have seen teachers show young children how to use their “inside voice,” “six-inch voice,” or “whisper voice.” One teacher said and then demonstrated, “If you have to interrupt me while I’m working with other children, stand quietly beside me until I can help you.” Be consistent in responding to students. If students are supposed to raise their hands, don’t call on those who break the rules. In these ways you will help students learn the rules of communication in the school context.

CULTURAL DISCONTINUITY. What happens when students’ values, participation structures, and learning preferences are in conflict with those espoused in mainstream school culture? After all, there is no such thing as a value-free learning environment (Christopher et al., 2014). Kenneth Tyler and his colleagues (2008) refer to this phenomenon as *cultural discontinuity*, which they define as “a school-based behavioral process where the cultural value-based learning preferences and practices of many ethnic minority students—those typically originating from home or parental socialization activities—are discontinued at school” (p. 281). Some learners who arrive at school have difficulty finding their own values reflected in the school culture, which is predominantly based on White, middle-class norms. Consequently, some students “learn quickly that they are expected to divorce themselves from their culture in order to be academically successful,” as Christopher Emdin (2016) poignantly asserts in his book, *For White Folks Who Teach in the Hood* (p. 13). What is the cost to students of being in a school culture with dissimilar values? “A loss of their dignity and a shattering of their personhood,” says Emdin. “Urban youth who enter schools seeing themselves as smart and capable are confronted by curriculum that is blind to their realities and school rules that seek to erase their culture” (p. 13). Such students learn that they must conform or else risk becoming invisible and devalued in the eyes of their teachers and peers.

Lessons for Teachers: Teaching Every Student

To be effective, instruction should be coupled with humility and respect for cultural differences (Delpit, 2012). The set of cultural behaviors and values that works in one context may not work in another. That does not mean that one is correct and the other is not. How will you understand and build on all the cultures of your students? How will

Sociolinguistics The study of the formal and informal rules for how, when, about what, to whom, and how long to speak in conversations within cultural groups.

Pragmatics The rules for when and how to use language to be an effective communicator in a particular culture.

Participation structures The formal and informal rules for how to take part in a given activity.

you deal with many different linguistic backgrounds? Here are several general teaching principles to guide you in finding answers to these questions.

KNOW YOURSELF. Becoming familiar and at ease with your own racial and ethnic heritage, cultural and linguistic background, and gender and sexuality are essential to your being able to create a safe space for students to do the same. Self-awareness also involves questioning the assumption that your values and experiences are the “norm” and therefore are the yardstick by which others should be measured. Peggy McIntosh (2009) encourages all teachers—White teachers in particular—to explore their own varied identities. This means reflecting on the ways in which we, in our unique and intersecting racial, economic, ethnic, religious, gender, and sexual identities (just to name a few) have reaped advantages from and disadvantages from the various systems of power around us. Let me underscore this point: To varying degrees, *all people face both unearned privileges and unearned disadvantages in their lives tied to the ways their identities are valued by others* in different contexts. Take a moment to return to the Stop & Think activity earlier in this chapter. How has some aspect of your identity advantaged you? How has some aspect of your identity led to disadvantages? How can this help you to understand your students’ experiences?

KNOW YOUR STUDENTS. We must learn who our students are and understand the legacies they bring (Delpit, 2003). Nothing you read in a chapter on cultural differences will teach you enough to understand the lives of all your students. If you can take other courses in college or read about other cultures, I encourage you to do it. But reading and studying are not enough. You should get to know your students’ families and communities. Elba Reyes, a successful bilingual teacher for children with special needs, describes her approach:

Usually I find that if you really want to know a parent, you get to know them on their own turf. This is key to developing trust and understanding the parents’ perspective. First, get to know the community. Learn where the local grocery store is and what the children do after school. Then schedule a home visit at a time that is convenient for the parents. The home environment is not usually as laden with failure. I sometimes observed the child being successful in the home, for example, riding a bicycle or helping with dinner. (Bos & Reyes, 1996, p. 349)

Try to spend time with students and parents on projects outside school. Ask parents to help in class or to speak to your students about their jobs, their hobbies, or the history and heritage of their ethnic group. Don’t wait until a student is in trouble to have the first meeting with a family member. Watch for and listen to the ways that your students interact in large and small groups. Have students write to you, and write back to them. Eat lunch with one or two students. Spend some nonteaching time with them.

RESPECT YOUR STUDENTS. From knowledge should come respect for your students’ learning strengths—for the struggles they face and the obstacles they have overcome. We must believe in our students (Delpit, 2003). For a child, genuine acceptance is a necessary condition for developing self-esteem. Sometimes the self-image and occupational aspirations of some children actually decline in their early years in public school, probably because of the emphasis on majority culture values, accomplishments, and history. One solution is to engage in what Emdin (2016) calls “reality pedagogy—an approach to teaching and learning that has a primary goal of meeting each student on his or her own cultural and emotional turf” (p. 27). By inviting students to bring their group’s culture into the classroom (in the form of literature, art, music, or any cultural knowledge), teachers can help students maintain a sense of pride in their cultural group. This integration of culture must be more than the “tokenism” of sampling ethnic foods or wearing costumes. Students should teach and learn with others about the socially and intellectually important contributions of various groups. Many excellent references provide background information, history, and teaching strategies for different groups of students (e.g., Banks, 2014; Emdin, 2016; Gay, 2000; Irvine & Armento, 2001; Ladson-Billings, 1995). And remember that this extends beyond ethnic group membership. It is equally important for learners to see members of other groups (e.g., sexual minority adults) represented in school curricula.

MyLab Education
Video Example 6.5

The teacher in this video uses a community building writing activity with her students. Her teaching practices model principles for instruction in a multicultural classroom: know your students, respect your students, teach your students.

TEACH YOUR STUDENTS. The most important thing you can do for your students is teach them to read, write, speak, compute, think, and create—through constant, rigorous, culturally connected instruction (Delpit, 2003). A strong emphasis on academics and high expectations combined with caring support for students is a key (Palardy, 2013). Beware of how hidden biases can creep in. Sometimes, in an attempt to be compassionate or to relieve the stress on students at risk, teachers give these students more positive feedback than they would privileged students. This well-intended but overly positive feedback can contribute to lowering expectations and reducing the academic challenge for these students (Harber et al., 2012). Too often, goals for students with low SES or from ethnic minority groups have focused exclusively on basic skills. Students are taught words and sounds, but the meaning of the story is supposed to come later. Read the *Guidelines: Culturally Relevant Teaching* for more ideas.

And finally, teach students directly about how to be students. In the early grades, this could mean directly teaching the courtesies and conventions of the classroom: how to get a turn to speak, how and when to interrupt the teacher, how to whisper, how to get help in a small group, how to give an explanation that is helpful, how to respect difference when interacting with others. In the later grades, it may mean teaching the

GUIDELINES

Culturally Relevant Teaching

Experiment with different grouping arrangements to encourage social harmony and cooperation.

Examples

1. Try “study buddies” and pairs.
2. Organize heterogeneous groups of four or five.
3. Establish larger teams for older students.

Provide a range of ways to learn material to accommodate a range of learning styles.

Examples

1. Give students verbal materials at different reading levels.
2. Offer visual materials—charts, diagrams, and models.
3. Provide tapes for listening and viewing.
4. Set up activities and projects.

Teach classroom procedures directly, even ways of doing things that you thought everyone would know.

Examples

1. Tell students how to get the teacher’s attention.
2. Explain when and how to interrupt the teacher if students need help.
3. Show which materials students can take and which require permission.
4. Demonstrate acceptable ways to disagree with or challenge another student.

Learn the meaning of different behaviors for your students.

Examples

1. Ask students how they feel when you correct or praise them. What gives them this message?

2. Talk to family and community members and other teachers to discover the meaning of expressions, gestures, or other responses that are unfamiliar to you.

Emphasize meaning in teaching.

Examples

1. Make sure students understand what they read.
2. Try storytelling and other modes that don’t require written materials.
3. Use examples that relate abstract concepts to everyday experiences; for instance, relate negative numbers to being overdrawn in your checkbook.

Get to know the customs, traditions, and values of your students.

Examples

1. Use holidays as a chance to discuss the origins and meaning of traditions.
2. Analyze different traditions for common themes.
3. Attend community fairs and festivals.

Help students detect racist, classist, sexist, and homophobic messages.

Examples

1. Analyze curriculum materials for biases.
2. Make students “bias detectives,” reporting comments from the media.
3. Discuss the ways that students communicate biased messages about each other, and decide what should be done when this happens.
4. Capitalize on teachable moments. Discuss expressions of prejudice such as anti-Semitism or homophobia when they arise in the media, in curricular materials, or in class.

academic language and study skills that fit your subject. You can ask students to learn “how we do it in school” without violating the third principle—respect your students. Ways of asking questions around the kitchen table at home may be different from ways of asking questions in school, but students can learn both ways, without deciding that either way is superior. And you can expand ways of doing it in school to include more possibilities.

MyLab Education Self-Check 6.5

▼ SUMMARY

Today's Diverse Classrooms (pp. 246–250)

What is culture, and how does cultural diversity affect learning and teaching? There are many conceptions of culture, but most include the knowledge, skills, rules, traditions, beliefs, and values that guide behavior in a particular group of people: Culture is a program for living. Everyone is a member of many cultural groups, defined in terms of geographic region, nationality, ethnicity, race, gender, social class, and religion. Membership in a particular group does not determine behavior or values, but makes certain values and kinds of behavior more likely. Wide variations exist within each group. You met two individuals, Ternice and Jessie, who embody that diversity.

The differences between cultures may be very obvious, tip-of-the iceberg characteristics, or they may be very subtle, below-the-surface differences. When subtle cultural differences meet, misunderstandings and conflicts are common. These conflicts can happen when the values and competencies of the dominant, mainstream culture are used to determine what is considered “normal” or appropriate behavior in schools. In these cases, children who have been socialized in a different culture may be perceived as acting inappropriately, not following the rules, or being rude and disrespectful.

Economic and Social Class Differences (pp. 250–257)

What is SES, and how does it differ from social class? Social class reflects a group's prestige and power in a society. Most people are aware of the social class that they share with similar peers. Sociologists use the term *SES* for variations in wealth, power, control over resources, and prestige. Socioeconomic status is determined by several factors—not just income—and often overpowers other cultural differences. No single variable is an effective measure of SES, but most researchers identify four general levels of SES: upper, middle, working, and lower classes. The main characteristics of these different SES levels are summarized in Table 6.1.

What is the relationship between SES and school achievement? Socioeconomic status and academic achievement are moderately correlated. Students of all ethnic groups with high SES show higher average levels of achievement on test scores and stay in school longer than students with low SES. The longer the child is in poverty, the stronger the impact is on achievement. Why is there a correlation between SES and school achievement? Students with low SES may experience inadequate health care, teachers' lowered expectations of them, low self-esteem,

learned helplessness, participation in resistance cultures, school tracking, understimulating home environments, and summer setbacks. This last striking finding is that children with low SES lose academic ground outside school over the summer, whereas children with higher SES continue to advance.

Ethnicity and Race in Teaching and Learning (pp. 257–267)

Distinguish between ethnicity and race. Ethnicity (culturally transmitted behavior) and race (a socially constructed categorization based on physical traits) are significant categories people use to describe themselves and others. Ethnic or racial minority groups (either numerically or historically marginalized) are rapidly increasing in population.

How can differences in the ethnicity of teachers and students affect school performance? Conflicts can arise from differences between teachers and students in culture-based beliefs, values, and expectations. Cultural conflicts are usually about below-the-surface differences, because when subtle cultural differences meet, misunderstandings are common. Students in some cultures learn attitudes and behaviors that are more consistent with school expectations. Differences in cognitive and academic abilities among ethnic groups are largely the legacy of racial segregation and continuing prejudice and discrimination.

Distinguish among prejudice, discrimination, and stereotype threat. Prejudice is a rigid and unfair generalization—a prejudgment or attitude—about an entire category of people. Prejudice may target people in particular racial, ethnic, religious, political, geographic, or language groups, or it may be directed toward the gender or sexual orientation of the individual. Discrimination is unequal treatment of or actions toward particular categories of people. Stereotype threat is the extra emotional and cognitive burden that your performance in an academic situation might confirm a stereotype that others hold about you. It is not necessary that the individual even believe the stereotype. All that matters is that the person is aware of the stereotype and cares about performing well enough to disprove its unflattering implications. In the short run, the fear that you might confirm a negative stereotype can induce test anxiety and undermine performance. Over time, experiencing stereotype threat may lead to disidentification with schooling and academic achievement.

Gender in Teaching and Learning (pp. 267–275)

What are gender identity and gender roles, and how do they develop? Gender identity is a personal view of one's self along the female-to-male continuum. Gender roles refer to a set of stereotypically masculine or feminine characteristics and behaviors. The differential behavior of parents and teachers toward male and female children and the larger social environment influence children's understanding of their gender roles. Through their interactions with family, peers, teachers, and the environment in general, children begin to form gender schemas, or organized networks of knowledge about what it means to be male or female.

How are gender biases communicated? In children's books, there are more males in the titles and the illustrations, and the characters (especially the boys) continue to behave in stereotypical ways. Girl characters sometimes cross gender roles to be more active, but boy characters seldom show "feminine" expressive traits. Some overrepresentation of gender exists in television commercials and online media, too. Teachers interact more with boys in both positive and negative ways. Lately some educators have claimed that schools are not supportive of boys, and same-sex classrooms have been suggested as an answer. The research on the value of these classrooms is mixed.

What are the stages of developing one's sexual orientation? Stages of developing a sexual orientation can also follow a pattern from discomfort to confusion to acceptance, particularly for sexual minority (gay, lesbian, bisexual, and transgender) students. Some researchers contend that one's sexual orientation is not always permanent and can change over the years.

Creating Culturally Compatible Classrooms (pp. 276–284)

What is multicultural education? Multicultural education is a field of study designed to increase educational equity for all students. According to the multicultural ideal, America should be transformed into a society that values diversity. James Banks suggests that multicultural education has five dimensions: integrating content, helping students understand how knowledge is influenced by beliefs, reducing prejudice, creating social structures in schools that support learning and development for all students, and using teaching methods that reach all students.

What is culturally relevant pedagogy? Gloria Ladson-Billings (1995, 2004) describes culturally relevant teaching that rests on three propositions: Students must experience academic success, develop/maintain their cultural competence, and develop a critical consciousness to challenge the status quo.

How can teachers build on the strengths of their students? Two strands of elements bind students to their classroom community. One strand emphasizes the self-agency of students—their capacity to set and pursue goals. This includes academic self-efficacy, self-control, and self-determination. The second strand emphasizes caring and connected relationships with the teacher, peers, and the home.

What are some aspects of diversity in learning? Teachers should pay attention to the social organization and participation structures in their classes and teach students directly how to be successful in these structures, strategically use information about students' cultural values and learning preferences, avoid cultural discontinuities in class, and know themselves and their students as individuals with complex identities. These accomplishments can lead to respecting every student and teaching her or him effectively.

MULTIPLE-CHOICE QUESTIONS

- Which of the following statements regarding the relationship between socioeconomic status (SES) and academic achievement is TRUE?
 - The average correlation between SES and academic achievement scores is strong, typically ranging from 0.60 to 0.80.
 - The positive relationship between SES and academic performance is much stronger for minority social groups than for majority social groups.
 - The lower the SES of the child, the stronger the impact on their academic performance.
 - One reason wealthy children have better academic outcomes is their higher motivation to perform better.
- Scholars generally agree that no single cause is to blame for why wealthy and economically disadvantaged children differ in their academic performance. Which of the following reasons is NOT supported by research?
 - Poorer children experience a wide range of stressors and health problems, which accounts for their lower performance at school.
 - Teachers often hold biased beliefs about students from low SES, assuming that they are academically incapable, and, therefore attend less to their needs.
 - Students from high SES are more likely to be a part of resistance culture, where they have a higher tendency to resist negative influences of others, and succeed in school.
 - Children from the lower SES families tend to spend more time watching television and less time on books and computers.
- Thuli is teaching mathematics to the seventh grade. There are 35 students, about half of whom are boys, and she has chosen to offer extra learning support to the girls. Why do you think she has decided to do this?
 - Thuli favors the girls over the boys in her class.
 - There are too many students in the class to offer learning support to all.
 - Thuli assumes that girls in general are less capable in mathematics. Thus, she is biased.
 - Thuli assumes that the boys are rich and hence, don't require the extra guidance.

- Mr. Vergheze asked students in his class about their career ambitions. Yati expressed her desire to become a computer scientist in the future. A few students discouraged her claiming computer scientist jobs were for men and told her to instead consider more "feminine" career paths, such as nursing. What can Mr. Vergheze do to address the situation?
 - He should emphasize that career choice is not determined by the social group (ethnic/racial/gender) one belongs to.
 - He should promote growth mindset in class, telling his students that with adequate effort, everyone can reach their career goals.
 - He should make all his students write self-affirmation essays stating that they can succeed in their chosen career path.
 - He should provide a counter narrative by claiming computer science to be a feminine field so as to balance the view held by the students.

CONSTRUCTED-RESPONSE QUESTIONS

Case

Bia Sousa moved from Portugal to South Africa while she was in the tenth grade. Her schooling was comparable to the schooling system in South Africa. Her teacher, Ms. June Senekal, was worried about her social adjustment. She noticed that Bia was involved in a same-sex romantic relationship with one of the students in her school. The other students in Ms. Senekal's class would often bully Bia, and exclude her from their social interactions. As the year progressed, she became distant and isolated. Ms. Senekal had a difficult time interacting with her. She decided that she needed to be proactive in finding a solution.

- Discuss the situation that has led Bia to become distant and isolated.
- What could Ms. Senekal, as an individual, do to better equip herself to support LGBTQ students?

MyLab Education Licensure Exam

▼ WHAT WOULD THEY DO?

TEACHERS' CASEBOOK White Girls Club

Here is how some expert teachers responded to the situation described at the beginning of the chapter about the "White Girls Club."

LAUREN ROLLINS • First-Grade Teacher

Boulevard Elementary School, Shaker Heights, OH

Discrimination of any kind will not be tolerated in my classroom! I would attack this unfortunate situation through a variety of different approaches—whole-class instruction, private small-group discussions, and one-on-one meetings with my new student and her parents. I would start my whole-class lesson by passing out candy (or some other desired object—stickers, pencils, etc.) to one chosen group of people—only boys, students with brown eyes, etc. I would purposely choose a group that excluded the girls who have formed the "White Girls Club." This activity would spark a conversation with the class about how unfair it is that one group of students got to do something that another group did not. We would talk about how the excluded group felt by this slight and why it is important not to discriminate against people for any reason. I would also include a read-aloud of a children's book that supported this topic. I would stop throughout my reading to discuss the feelings of the different characters in the book. Next, I would meet privately with the girls who have formed the club. I would remind them that excluding people from a group is unacceptable and will not be tolerated by me. Either everyone gets to play, or no one does. Last, I would meet with my new student and her parents. I would ask her to give me the names of a few students in my class with whom she would be interested in building a relationship. I would encourage her parents to set up one-on-one play dates for their daughter outside of school with the hope of building relationships.

PAULA COLEMERE • Special Education Teacher—English, History

McClintock High School, Tempe, AZ

In one of my favorite lessons for the beginning of the year, I give each student five mixed beans and have students choose which is the "best" one. We then discuss why they chose the bean as the best and discuss the differences in beans before connecting to people. After the discussion, we role-play different scenarios that deal with diversity; this is a good lesson because it addresses self-esteem in addition to diversity. While all students can use a boost to self-esteem, it would hopefully help the new girl to feel better about the situation. This lesson can be tailored to younger or older students. Because these students are young, I would hope this would be a gentle way for the girls in the "club" to see that what they have been doing is wrong. My next step would be to conference with the girls and mediate if necessary.

PAUL DRAGIN • ESL Teacher Grades 9–12

Columbus East High School, Columbus, OH

Based on the observations, I would not hesitate to act quickly in this situation of exclusion. Based on the age group of the

students, I would attack this problem two ways initially. I would spend classroom time talking about building community and present some scenarios and videos about how it feels to be excluded or left out. With children at this impressionable age, this troubling dilemma may leave an indelible mark on some if handled in such a way that they internalize the feelings that the excluded student is inevitably confronted with being the "other." I would contact the parents of the girls who made the "White girls club" comment and let them know what I overheard and witnessed regarding the new student. Hopefully, this could turn an unfortunate situation into a great learning opportunity that would stick with the students whenever they are confronted with someone racially, ethnically, or culturally different from them.

JESSICA N. MAHTABAN • Eighth-Grade Math

Woodrow Wilson Middle School, Clifton, NJ

My immediate response would be to investigate the "club." I could talk to each girl individually and ask why she started the club as well as why they felt it was important to exclude people from their club. Also, I must make sure the parents, administration, and counselors are aware of the situation as well.

It is my job to explain to my students as best I can that it's not polite to exclude anyone. I would give them different scenarios about exclusion and ask for them to reflect on their personal feelings for each scenario. We would discuss in groups as well as the whole class about the scenarios and their feelings. Problem solving together would be the best approach to finding various solutions to problems as well as figuring out who can help them in different situations. Hopefully, by the end of these lessons, each student will understand that our classroom is a family, and that, as a family, we celebrate differences—not segregate.

SARA VINCENT • Special Education Teacher

Langley High School, McLean, VA

Discrimination and racism often occur because of ignorance. The best solution to minimize discrimination is educating individuals about diverse cultures. The teacher can invite the new student's family into the classroom to talk about their backgrounds and experiences, or she can have the entire class complete a project on family history. Once the other students in the classroom learn more about the new student's culture, they will be more likely to accept her differences and understand that she is not much different from them. In addition, the teacher can have the new student be team leader at recess or in the classroom so that she will not be picked last. This will help her gain confidence in befriending her peers. While the teacher attempts to focus on positive aspects of educating her students, she should make the administration aware of the "White Girls Club" situation. Administrators should intervene and bring attention to the situation if the troubling behaviors of the other girls continue.

chapter seven

BEHAVIORAL VIEWS OF LEARNING

WHAT WOULD YOU DO?

TEACHERS' CASEBOOK: Sick of Class

One of your students asks for permission to see the school nurse at least twice a week. According to the nurse, most of his complaints have been groundless. True, once he was coming down with the flu, but 9 out of 10 times, nothing has been wrong at all. Recently you have noticed that he tends to “get sick” during oral assignments or when he has to speak before the class. What steps would you take to deal with this situation?

CRITICAL THINKING

- Could this be a case of a classically conditioned phobia? If so, what would you do?
- What functions might this behavior be serving?
- How would you support more positive behaviors and help the student find other ways to meet his needs?
- Would giving rewards or administering punishments be useful in this situation? Why or why not?

MIDNIGHTBLUES/Shutterstock

OVERVIEW AND OBJECTIVES

We begin this chapter with a general definition of learning that takes into account the opposing views of different theoretical groups. We will highlight one group, the behavioral theorists, in this chapter and another major group, the cognitive theorists, in Chapters 8 and 9; then, we will look at constructivism in Chapter 10 and social cognitive views in Chapter 11. As you can see, there are many ways to look at learning, and each has something to offer educators.

Our discussion in this chapter will focus on four behavioral learning processes: contiguity, classical conditioning, operant conditioning, and observational learning, with the greatest emphasis placed on the last two processes. After examining the implications of applied behavior analysis for teaching, we look at current directions in behavioral approaches to learning—functional behavioral assessments, positive behavior support, and self-management. Finally, we investigate Bandura’s challenge to behavioral views of learning as well as other criticisms, cautions, and ethical considerations for educators.

By the time you have completed this chapter, you should be able to:

- Objective 7.1 Define learning from a behavioral perspective, including ties to neuroscience and the processes involved in learning through contiguity, classical conditioning, operant conditioning, and observational learning.
- Objective 7.2 Explain early views of learning through contiguity and classical conditioning and describe their implications for teaching.
- Objective 7.3 Explain operant conditioning, particularly the differences and similarities between positive and negative reinforcement and presentation and removal punishment and how reinforcement schedules affect learning.
- Objective 7.4 Apply behavioral approaches to modifying behavior in and out of the classroom using applied behavioral analysis approaches to encourage and discourage behaviors, shaping, positive practice, contingency contracts, token reinforcement, group consequences, and the appropriate use of punishment.
- Objective 7.5 Apply functional behavioral assessment, positive behavioral supports, and self-management techniques.
- Objective 7.6 Evaluate contemporary challenges to behavioral theories of learning and address concerns about their application.

Summary and Key Terms

Teachers' Casebook—Sick of Class: What Would They Do?

Learning Process through which experience causes permanent change in knowledge or behavior.

Behavioral learning theories Explanations of learning that focus on external events as the cause of changes in observable behaviors.

UNDERSTANDING LEARNING

When we hear the word *learning*, most of us think of studying and school. We think about subjects or skills we intend to master, such as algebra, Spanish, chemistry, or karate. But learning is not limited to school. We learn every day of our lives. Babies learn to kick their legs to make the mobile above their cribs move, young girls learn the lyrics to all their favorite Taylor Swift songs, middle-aged people like me learn to change their diet and exercise patterns, and every few years we all learn to find a new style of dress attractive when the old styles (the ones we once loved) go out of fashion. This last example shows that learning is not always intentional. We don't try to like new styles and dislike old ones; it just seems to happen that way. We don't intend to become nervous when we step onto a stage, yet many of us do. So what is this powerful phenomenon called *learning*?

In the broadest sense, **learning** occurs when experience (including practice) causes a relatively permanent change in an individual's knowledge, behavior, or potential for behavior. The change may be deliberate or unintentional, for better or for worse, correct or incorrect, and conscious or unconscious (Mayer, 2011; Schunk, 2016). To qualify as learning, this change must be brought about by experience—by the interaction of a person with his or her environment. Changes simply caused by maturation, such as growing taller or turning gray, do not qualify as learning. Temporary changes resulting from illness, fatigue, drugs, or hunger are also excluded from a general definition of learning. A person who has gone without food for 2 days does not learn to be hungry. Of course, learning plays a part in how we respond to hunger.

Our definition specifies that the changes resulting from learning take place in the individual's knowledge, behavior, or potential for behavior. Most psychologists would agree with this statement, but cognitive psychologists tend to emphasize the change in knowledge, whereas behavioral psychologists focus on the change in behavior. The potential for behavior means that learning can take place even if the individual does not always act on the change. The potential is there, even if the behavior does not occur until the situation or motivation is right. (S. B. Klein, 2015).

The psychologists discussed in this chapter favor **behavioral learning theories**. The behavioral view focuses on changes in behavior and emphasizes the effects of external

events on the individual. Some early behaviorists such as J. B. Watson (1919) took the radical position that because thinking, intentions, and other internal mental events could not be seen or studied rigorously and scientifically, these "mentalisms," as he called them, should not even be included in an explanation of learning.

Sometimes people associate behavioral explanations of learning with disturbing teaching approaches that fall under the heading of *behavior modification*, which sounds pretty bad. Behavior modification evokes images of brain washing, punishment, and even shock therapy. As you will see in this chapter, a more accurate term for the teaching and therapy approaches based on behavioral views of learning is *applied behavior analysis* (Alberto & Troutman, 2017). Before we explore behavioral learning theories and the strategies based on these perspectives, let's address some important ethical considerations.

Ethical Issues

The ethical questions related to the use of the strategies described in this chapter are similar to those raised by any process that seeks to influence people. What are the goals? How do these goals correspond with those of the teacher or school? What effect will a strategy have on the individuals involved? Is too much control being given to the teacher, or to a majority?

GOALS. The strategies described in this chapter could be applied exclusively to teaching students to sit still, raise their hands before speaking, and remain silent at all other times (Winett & Winkler, 1972). This certainly would be an unethical use of the techniques. It is true that a teacher may need to establish some organization and order, but stopping with improvements in conduct will not ensure academic learning. On the other hand, in some situations, supporting academic learning may lead to improvements in conduct. Whenever possible, teachers should emphasize applying the strategies to academic learning. Academic improvements generalize to other situations more successfully than do changes in classroom conduct.

STRATEGIES. Punishment, discussed later in this chapter, can have negative side effects: It can serve as a model for aggressive responses, and it can encourage negative emotional reactions. Punishment is unnecessary and even unethical when positive approaches, which have fewer potential dangers, might work as well. When simpler, less-restrictive procedures fail, then more complicated techniques should be tried.

A second consideration in the selection of a strategy is the impact of the strategy on the individual student. For example, some teachers arrange for students to be rewarded at home with a gift or special activities based on good work in school. But if a student has a history of being severely punished at home for bad reports from school, a home-based reward program might be very harmful to that student. Reports of unsatisfactory progress at school could lead to increased abuse at home. Keep these cautions and considerations in mind as you read about the strategies in this chapter. Before we look in depth at behavioral explanations of learning, let's step into an actual classroom and note the possible results of learning.

Learning Is Not Always What It Seems

After weeks of working with her cooperating teacher in an eighth-grade social studies class, Elizabeth was ready to take over on her own. As she moved to the front of the room, she saw another adult approach the classroom door. It was Mr. Ross, her supervisor from college. Elizabeth's neck and facial muscles suddenly became very tense.

"I've stopped by for my first observation," Mr. Ross said. "I couldn't reach you last night to tell you."

Elizabeth tried to hide her reaction, but her hands trembled as she gathered the notes for the lesson. She turned to face her students and introduced the day's topic.

"Let's start today with a kind of game. I will say some words, then I want you to tell me the first words you can think of, and I will write them on the board. Don't all speak at once, though. Wait until someone else has finished before you say your word. Okay, here is the first word: Slavery."

"Civil War." "Lincoln." "Freedom." "Emancipation Proclamation." The answers came quickly, and Elizabeth was relieved to see that the students understood the game.

"All right, very good," she said. "Now try another one: South."

"South Carolina." "South Dakota." "South Park," "No, the Confederacy, you dummy." "Slavery," "*Free State of Jones*," "Matthew McConaughey." With this last answer, a ripple of laughter moved across the room.

"Matthew McConaughey!" Elizabeth sighed dreamily. Then she laughed too. Soon all the students were laughing. "Okay, settle down," Elizabeth said. "Here is another word: North."

"Bluebellies." The students continued to laugh. "Jelly Bellies." "Belly-dancers." More laughter and a few inappropriate gestures.

"Just a minute," Elizabeth pleaded. "These ideas are getting a little off base!"

“Off base? Baseball,” shouted the boy who had first mentioned Matthew McConaughey. He stood up and started throwing balls of paper to a friend in the back of the room, simulating the style of Clayton Kershaw.

“The San Francisco Giants.” “No, the LA Dodgers, dummy.” “Ball games.” “Hot dogs.” “Popcorn.” “Movies.” “*Free State of Jones*.” “Matthew McConaughey.” The responses now came too fast for Elizabeth to stop them. For some reason, the “Matthew McConaughey” line got an even bigger laugh the second time around, and Elizabeth suddenly realized she had lost the class.

“Okay, because you know so much about the Civil War, close your books and take out a pen,” Elizabeth said, obviously angry. She passed out the worksheet that she had planned as a cooperative, open-book project. “You have 20 minutes to finish this test!”

“You didn’t tell us we were having a test!” “This isn’t fair!” “We haven’t even covered this stuff yet!” “I didn’t do anything wrong!” There were moans and disgusted looks, even from the most mellow students. “I’m reporting you to the principal; it’s a violation of students’ rights!”

This last comment hit hard. The class had just finished discussing human rights as preparation for this unit on the Civil War. As she listened to the protests, Elizabeth felt terrible. How was she going to grade these “tests”? The first section of the worksheet involved facts about events during the Civil War, and the second section asked students to create a news-style program interviewing ordinary people touched by the war.

“All right, all right, it won’t be a test. But you do have to complete this worksheet for a grade. I was going to let you work together, but your behavior this morning tells me that you are not ready for group work. If you can complete the first section of the sheet working quietly and seriously, you may work together on the second section.” Elizabeth knew that her students would like to work together on writing the script for the news interview program.

Elizabeth was afraid to look back at her supervisor. What was he writing on his observation form?

MyLab Education Video Example 7.1

A kindergarten teacher begins on the first day to teach her students the procedures for good listening. Observe this example of the principle of contiguity and identify the stimulus used by the teacher.

Learning by Association (I, A1)

Quite a bit of classroom learning can be attributed to contiguity (i.e., learning by association). What are some things that you might have learned because your teacher paired certain stimuli (e.g., names of the letters of the alphabet)?

Contiguity Association of two events because of repeated pairing.

Stimulus Event that activates behavior.

Response Observable reaction to a stimulus.

It appears, on the surface at least, that very little learning of any sort was taking place in Elizabeth’s classroom. Elizabeth had some good ideas, but she also made some mistakes in her application of learning principles. We will return to this episode several times in the chapter to analyze various aspects of what took place. To get us started, four events can be singled out, each possibly related to a different learning process.

First, the students were able to associate the words *Carolina*, *Dakota*, and *Park* with the word *South*. Second, Elizabeth’s hands trembled when her college supervisor entered the room. Third, one student continued to disrupt the class with inappropriate responses. And fourth, after Elizabeth laughed at a student’s comment, the class joined in her laughter. The four learning processes represented are contiguity, classical conditioning, operant conditioning, and observational learning. In the following pages we will examine these four kinds of learning, starting with contiguity.

EARLY EXPLANATIONS OF LEARNING: CONTIGUITY AND CLASSICAL CONDITIONING

One of the earliest explanations of learning came from Aristotle (384–322 BC). He said that we remember things together (1) when they are similar, (2) when they contrast, and (3) when they are contiguous. This last principle is the most important, because it is included in all explanations of *learning by association*. The principle of **contiguity** states that when two or more sensations occur together often enough, they will become associated. Later, when only one of these sensations (a **stimulus**) occurs, the other will be remembered too (a **response**) (S. B. Klein, 2015; Rachlin, 1991). For example, when Elizabeth said “South,” students associated the words “Carolina,” “Dakota,” and “Park.” They had heard these words used together many times. Other processes may also be involved when students learn these phrases, but contiguity is a factor. Contiguity also plays a major role in another learning process best known as *classical conditioning*.

STOP & THINK Close your eyes and focus on a vivid image of the following: The smell of French fries cooking. A time you were really embarrassed in school. The taste of chocolate fudge. The sound of a dentist's drill. What did you notice as you formed each of these images? •

If you are like me, imagining the sound of the dentist's drill tightens your neck muscles. I can actually salivate when I imagine salty fries or smooth rich chocolate (especially because it is 6:00 p.m. and I haven't had dinner yet). The first embarrassing school incident I remembered was falling flat as I did a cartwheel in front of the whole high school. A small cringe still accompanies the memory. **Classical conditioning** focuses on the learning of involuntary emotional or physiological responses such as fear, increased muscle tension, salivation, or sweating. These sometimes are called **respondents** because they are automatic responses to stimuli. Through the process of classical conditioning, humans and animals can be trained to react involuntarily to a stimulus that previously had no effect—or a very different effect—on them. The stimulus comes to elicit, or bring forth, the response automatically.

Classical conditioning was discovered in the 1920s by Ivan Pavlov, a Russian physiologist who was trying to determine how long it took a dog to secrete digestive juices after it had been fed. But the intervals of time kept changing. At first, the dogs salivated as expected while they were being fed. Then the dogs began to salivate as soon as they saw the food, and finally they salivated as soon as they heard the scientists walking toward the lab. Pavlov decided to make a detour from his original experiments and examine these unexpected interferences or “psychic reflexes” as he called them at first.

In one of his early experiments, Pavlov began by sounding a tuning fork and recording a dog's response. As expected, there was no salivation. At this point, the sound of the tuning fork was a **neutral stimulus** because it brought forth no salivation. Then Pavlov fed the dog. The response was salivation. The food was an **unconditioned stimulus (US)** because no prior training or “conditioning” was needed to establish the natural connection between food and salivation. The salivation was an **unconditioned response (UR)**, again because it was elicited automatically—no conditioning required.

Using these three elements—the food, the salivation, and the tuning fork—Pavlov demonstrated that a dog could be *conditioned* to salivate after hearing the tuning fork. He did this by *contiguous* pairing of the sound with food. He sounded the fork and then quickly fed the dog. After Pavlov repeated this several times, the dog began to salivate after hearing the sound, but before receiving the food. Now the sound had become a **conditioned stimulus (CS)** that could bring forth salivation by itself. The response of salivating after the tone was now a **conditioned response (CR)**. One explanation for how this occurs focuses on expectations or predictability—the dog learns that the previously neutral stimulus (the sound of the tuning fork) now predicts the appearance of the US (the food), so the animal responds to the sound with an anticipatory response (salivating)—getting ready for or anticipating the food. The association or conditioning of the sound to salivating will occur as long as the sound is information that helps the dog expect “food is on the way” (Gluck, Mercado, & Myers, 2014; Rescorla & Wagner, 1972).

If you think that Pavlovian conditioning is of historical interest only, consider this excerpt from *USA Today* describing an advertising campaign for products aimed at “Gen Y,” those people born between 1977 and 1994:

Mountain Dew executives have their own term for this [advertising strategy]: the Pavlovian connection. By handing out samples of the brand at surfing, skateboard and snowboard tournaments, “There's a Pavlovian connection between the brand and the exhilarating experience,” says Dave Burwich, a top marketing executive at Pepsi, which makes Mountain Dew. (Horovitz, 2002, p. B2)

Maybe they could hand out math homework too!

Classical conditioning

Association of automatic responses with new stimuli.

Respondents Responses (generally automatic or involuntary) elicited by specific stimuli.

Neutral stimulus Stimulus not connected to a response.

Unconditioned stimulus (US) Stimulus that automatically produces an emotional or physiological response.

Unconditioned response (UR) Naturally occurring emotional or physiological response.

Conditioned stimulus (CS) Stimulus that evokes an emotional or physiological response after conditioning.

Conditioned response (CR) Learned response to a previously neutral stimulus.

GUIDELINES

Applying Classical Conditioning

Associate positive, pleasant events with learning tasks.

Examples

1. Emphasize group competition and cooperation over individual competition. Many students have negative emotional responses to individual competition that may generalize to other learning.
2. Make division drills fun by having students decide how to divide refreshments equally, then letting them eat the results.
3. Make voluntary reading appealing by creating a comfortable reading corner with pillows, colorful displays of books, and reading props such as puppets.

Help students to risk anxiety-producing situations voluntarily and successfully.

Examples

1. Assign a shy student the responsibility of teaching two other students how to distribute materials for map study.

2. Devise small steps toward a larger goal. For example, give ungraded practice tests daily, and then weekly, to students who tend to “freeze” in test situations.
3. If a student is afraid of speaking in front of the class, let the student read a report to a small group while seated, then read it while standing, then give the report from notes instead of reading it verbatim. Next, move in stages toward having the student give a report to the whole class.

Help students recognize differences and similarities among situations so they can discriminate and generalize appropriately.

Examples

1. Explain that it is appropriate to avoid strangers who offer gifts or rides, but safe to accept favors from adults when parents are present.
2. Assure students who are anxious about taking college entrance exams that this test is like all the other achievement tests they have taken.

Basics of Operant Conditioning (I, A1)

Be able to explain learning from the behavioral perspective. Incorporate concepts of classical and operant conditioning into your explanation. Have a firm grasp of the effects of reinforcement schedules on learning.

It is possible that many of our emotional reactions to various situations are learned in part through classical conditioning. Physicians have a term, *white coat syndrome*, that describes people whose blood pressure (an involuntary response) goes up when it is tested in the doctor's office, usually by someone in a white coat. Another example, Elizabeth's trembling hands when she saw her college supervisor, might be traced to previous unpleasant experiences during past evaluations of her performance. Now just the thought of being observed elicits a pounding heart and sweaty palms. Classical conditioning has implications for teachers as well as marketing managers. Remember that emotions and attitudes as well as facts and ideas are learned in classrooms. This emotional learning can sometimes interfere with academic learning. Procedures based on classical conditioning also can be used to help people learn more adaptive emotional responses, as the *Guidelines: Applying Classical Conditioning* suggest.

MyLab Education **Self-Check 7.1**

OPERANT CONDITIONING: TRYING NEW RESPONSES

Operants Voluntary (and generally goal-directed) behaviors emitted by a person or an animal.

Operant conditioning

Learning in which voluntary behavior is strengthened or weakened by consequences or antecedents.

So far, we have concentrated on the automatic conditioning of reflex-like responses such as salivation and fear. Clearly, not all human learning is so unintentional and not all responses or behaviors are so automatic. People actively “operate” on their environment. These deliberate actions are called **operants**. The learning process involved in operant behavior is called **operant conditioning** because we learn to behave in certain ways as we operate on the environment.

The person generally thought to be responsible for developing the concept of operant conditioning is B. F. Skinner (1953). Skinner began with the belief that the principles

of classical conditioning account for only a small portion of learned behaviors. Many human behaviors are operants, not respondents. Classical conditioning describes only how existing responses might be paired with new stimuli; it does not explain how new operant behaviors are acquired.

Behavior, like response or action, is simply a word for what a person does in a particular situation (please note, I use the words *behavior* and *response* to mean the same thing throughout this book). Conceptually, we may think of a behavior as sandwiched between two sets of environmental influences: those that precede it (its **antecedents**) and those that follow it (its **consequences**) (Skinner, 1950). This relationship can be shown very simply as antecedent–behavior–consequence, or A–B–C (Kazdin, 2008). As behavior is ongoing, a given consequence becomes an antecedent for the next A–B–C sequence. Research in operant conditioning shows that operant behavior can be altered by changes in the antecedents, the consequences, or both. Early work focused on consequences, often using rats or pigeons as subjects. We look at consequences first.

Types of Consequences

STOP & THINK Think back over teachers you have had who used rewards or punishments.

Try to remember different types of rewards:

- Concrete rewards (stickers, food, prizes, certificates)
- Activity rewards (free time, puzzles, free reading, computer game time)
- “Exemption” rewards (no homework, no weekly test)
- Social rewards (praise, recognition, leadership roles)

What about punishments?

- Loss of privileges (cannot sit where you want, cannot work with friends)
- Fines (lost points, grades, money)
- Extra work (homework, laps, push-ups) •

According to the behavioral view, consequences determine to a great extent whether a person will repeat the behavior that led to the consequences. The type and timing of consequences can strengthen or weaken behaviors. We will look first at consequences that strengthen behavior.

REINFORCEMENT. Although **reinforcement** is commonly understood to mean “reward,” this term has a particular meaning in psychology. A **reinforcer** is *any* consequence that strengthens the behavior it follows. So, by definition, reinforced behaviors increase in frequency or duration—that is, *how often* or *how long* the behaviors occur. Whenever you see a behavior persisting or increasing over time, you can assume the consequences of that behavior are reinforcers for the individual involved (Alberto & Troutman, 2017; S. B. Klein, 2015; Landrum & Kauffman, 2006). The reinforcement process can be diagrammed as follows:

We can be fairly certain that food will be a reinforcer for a hungry animal, but what about people? Whether the consequences of any action are reinforcing probably depends on the individual’s perception of the event and the meaning it holds for her or him. For example, students who repeatedly get sent to the principal’s office for misbehaving may be indicating that something about this consequence is reinforcing for them, even if it doesn’t seem desirable to you. By the way, Skinner did not speculate about why reinforcers increase behavior. He believed that it was useless to talk about “imaginary constructs” such as perceptions or meaning. Skinner simply described the tendency for a given operant behavior to increase after certain consequences (Skinner, 1953, 1989).

Antecedents Events that precede an action.

Consequences Events that follow an action.

Reinforcement Use of consequences to strengthen behavior.

Reinforcer Any event that follows a behavior and increases the chances that the behavior will occur again.

There are two types of reinforcement. The first, called **positive reinforcement**, occurs when the behavior or response leads to the *appearance or presentation* of a new stimulus (Alberto & Troutman, 2017). Examples of positive reinforcement include the behavior of a pigeon pecking on the red key leading to the presentation of food, a student falling out of his chair leading to cheers and laughter from classmates, or wearing a new outfit leading to compliments.

Notice that positive reinforcement can occur even when the response being reinforced (falling out of a chair) is not “positive” from the teacher’s point of view. Positive reinforcement of inappropriate responses occurs unintentionally in many classrooms. Teachers help maintain problem behaviors by inadvertently reinforcing them. For example, Elizabeth may have unintentionally reinforced problem responses in her class by laughing the first time the boy answered, “Matthew McConaughey.” The problem behavior may have persisted for other reasons, but the consequence of Elizabeth’s laughter could have played a role.

When the consequence that strengthens a behavior is the *presentation* (addition) of a new stimulus, the situation is defined as *positive reinforcement*. In contrast, when the consequence that strengthens a behavior is the *removal* (subtraction) of a stimulus, the process is called **negative reinforcement** (Alberto & Troutman, 2107). If a particular action leads to avoiding or escaping an aversive situation, the action is likely to be repeated in a similar situation. A common example is the car seatbelt buzzer. As soon as you put on your seatbelt, the irritating buzzer stops. The process is *reinforcement* because you *repeat* this “buckling up” action in the future. The kind of reinforcement is *negative* because the buckling up behavior *removed* (subtracted) an aversive buzzing stimulus.

Consider our opening case student who continually “gets sick” right before an oral presentation and then is sent to the nurse’s office. This behavior allows him to escape aversive situations—public speaking—so getting “sick” is being maintained, in part, through negative reinforcement. It is negative because getting sick *removed* the unpleasant stimulus (the oral report); it is reinforcement because the behavior that removed the stimulus (getting “sick”) increases or repeats in the future. It is also possible that classical conditioning plays a role. The student may have been conditioned to experience unpleasant physiological reactions to public speaking.

It is important to remember that the “negative” in negative reinforcement does not imply that the behavior being reinforced is necessarily negative or bad. The meaning is closer to that of “negative” numbers—*something is subtracted*. Try to associate positive and negative reinforcement with the *consequence* of *adding* or *subtracting* something following a behavior. That adding or subtracting has the *effect* of strengthening (reinforcing) the behavior.

PUNISHMENT. Negative reinforcement is often confused with punishment. To avoid this mistake, remember that the process of reinforcement (positive or negative) always involves *increasing* or *strengthening* behavior. **Punishment**, on the other hand, always involves *decreasing* or *suppressing* behavior. A behavior followed by a punisher is less likely to be repeated in similar situations in the future. Again, it is the effect that defines a consequence as punishment, and different people have different perceptions of what is punishing. One student may find suspension from school punishing, whereas another student wouldn’t mind the break at all. The process of punishment is diagrammed as follows:

Like reinforcement, punishment may take one of two forms. The first type has been called Type I punishment, but this name isn’t very informative, so I use the term **presentation punishment**. It occurs when presenting (adding) a stimulus following the behavior has the effect of suppressing or decreasing the behavior. When teachers reprimand students, assign extra work, or make students run extra laps, and so on, they are

MyLab Education Podcast 7.1

If a student continues to read the educational psychology textbook very closely and, as a result, continually gets good test scores, is this negative reinforcement or positive reinforcement? Textbook author Anita Woolfolk answers this question and others regarding negative reinforcement.

Positive reinforcement

Strengthening behavior by presenting a desired stimulus after the behavior.

Negative reinforcement

Strengthening behavior by removing an aversive stimulus when the behavior occurs.

Punishment Process that weakens or suppresses behavior.

Presentation punishment

Decreasing the chances that a behavior will occur again by presenting an aversive stimulus following the behavior; also called *Type I punishment*.

FIGURE 7.1

KINDS OF REINFORCEMENT AND PUNISHMENT

Negative reinforcement and punishment are often confused. It may help you to remember that reinforcement is always associated with increases in behaviors, and punishment always involves decreasing or suppressing behavior.

using presentation punishment. I call the other type of punishment (Type II punishment) **removal punishment** because it involves removing (subtracting) a stimulus. When teachers or parents take away privileges after a young person has behaved inappropriately, they are applying removal punishment. With both types, the effect is to decrease the behavior that led to the punishment. Figure 7.1 summarizes the processes of reinforcement and punishment.

Neuroscience of Reinforcement and Punishment

Why do reinforcement and punishment work? There are many theories. For example, some psychologists suggest that reinforcers are preferred activities or that they satisfy needs, whereas other psychologists believe that reinforcers reduce tension. You saw in Chapter 2 that we are learning more and more about the brain. Researchers conducting animal and human studies have discovered quite a bit about the areas of the brain involved with learning new behaviors. For example, parts of the cerebellum are involved in simple reflex learning, like learning to blink following a particular tone, and other parts of the brain are involved in learning how to avoid painful stimulation such as a shock (S. B. Klein, 2015; Schwartz, Wasserman, & Robbins, 2002). Other lines of research ask why animals and people will behave in certain ways to gain stimulation or reinforcers. Stimulation to certain parts of the brain will cause hungry rats to ignore food and keep doing whatever it takes to keep the stimulation coming. These same brain systems are associated with the pleasures people experience from many things, including food and music. It is likely that many parts of the brain and complex patterns

Removal punishment
Decreasing the chances that a behavior will occur again by removing a pleasant stimulus following the behavior; also called *Type II punishment*.

TABLE 7.1 • Five Reinforcement Schedules

SCHEDULE	DEFINITION	EXAMPLE	RESPONSE PATTERN	REACTION WHEN REINFORCEMENT STOPS
Continuous	Reinforcement after every response	Turning on the television; Buying candy from a vending machine	Rapid learning of response	Very little persistence; response disappears quickly
Fixed-interval	Reinforcement after a set period of time	Studying as weekly quiz approaches; Dishwashing cycle (dishes are clean after a specific time period)	Response rate increases as time for reinforcement approaches, then drops after reinforcement	Little persistence; response disappears quickly when time for reinforcement passes and no reinforcer appears
Variable-interval	Reinforcement after varying lengths of time	Pop quizzes; Texting (get an answer after variable time periods); Birding (variable times between spotting a new kind of bird)	Slow, steady rate of responding; very little pause after reinforcement	Greater persistence; slow decline in response rate
Fixed-ratio	Reinforcement after a set number of responses	Telemarketer gets a bonus after every 100 credit cards enrolled; Bake sale	Rapid response rate; pause after reinforcement	Little persistence; rapid drop in response rate when expected number of responses are given and no reinforcer appears
Variable-ratio	Reinforcement after a varying number of responses	Slot machines	Vary high response rate; little pause after reinforcement	Greatest persistence; response rate stays high and gradually drops off

Source: Based on information in Alberto, P. A., & Troutman, A. C. (2017). *Applied Behavior Analysis for Teachers* (9th ed.). Boston, MA: Pearson; Klein, S. B. (2015). *Learning: Principles and Applications* (7th ed.). Thousand Oaks, CA: Sage.

of activity allow us to enjoy some experiences, “learn to want them, and learn how to get them” (Bernstein & Nash, 2008, p. 187).

Reinforcement Schedules

When individuals are learning a new behavior, they will learn it faster if they are reinforced for every correct response. This is a **continuous reinforcement schedule**. Then, when they have mastered the new behavior, they will maintain it best if they are reinforced intermittently, now and then, rather than every time. An **intermittent reinforcement schedule** helps students to maintain skills without expecting constant reinforcement.

There are two basic types of intermittent reinforcement schedules. One—called an **interval schedule**—is based on the amount of time that passes between reinforcers. The other—a **ratio schedule**—is based on the number of responses learners give between reinforcers. Interval and ratio schedules may be either fixed (predictable) or variable (unpredictable). Table 7.1 summarizes the five possible reinforcement schedules (the continuous schedule and the four kinds of intermittent schedules).

What are the effects of different schedules? Speed of performance depends on control. If reinforcement is based on the number of responses you give, then you have more control over the reinforcement: The faster you accumulate the correct number of responses, the faster the reinforcement will come. A teacher who says, “As soon as you complete these 10 problems correctly, you may use your class iPad,” can expect

Continuous reinforcement schedule Presenting a reinforcer after every appropriate response.

Intermittent reinforcement schedule Presenting a reinforcer after some but not all responses.

Interval schedule Length of time between reinforcers.

Ratio schedule Reinforcement based on the number of responses between reinforcers.

higher rates of performance than a teacher who says, “Work on these 10 problems for the next 20 minutes. Then I will check your papers and those with 10 correct may use your class iPad.”

Persistence in performance depends on unpredictability. Continuous reinforcement and both kinds of fixed reinforcement (ratio and interval) are quite predictable. We come to expect reinforcement at certain points and are generally quick to give up when the reinforcement does not meet our expectations. To encourage persistence of response, variable schedules are most appropriate. A great example of student persistence on a variable schedule was presented in an article about Valorie Lewis, a member of the *USA Today* All-USA teacher team. Describing Lewis’s third-grade class, one of her colleagues said that the students are “afraid to be absent because they don’t want to take the chance they will miss anything. Mrs. Lewis doesn’t tell them when she is planning something special, so they have to be there every day just in case” (S. Johnson, 2008, p. 7D). If the reinforcement schedule is gradually changed until it becomes very “lean”—meaning that reinforcement occurs only after many responses or after a long time interval—then people can learn to work for extended periods without any reinforcement at all. Just watch gamblers playing slot machines to see how powerful a lean reinforcement schedule can be.

Reinforcement schedules influence how persistently we will respond when reinforcement is withheld. What happens when reinforcement is completely withdrawn?

EXTINCTION. In *classical conditioning*, the CR (conditioned response) is extinguished (disappears) when the CS (conditioned stimulus) appears, but the US (unconditioned response) does not follow—sound, but no food. In *operant conditioning*, a person or an animal will not persist in a certain behavior if the usual reinforcer is withheld long enough. The behavior will eventually be extinguished (stop). For example, if you repeatedly text someone but never get a reply, you may give up texting that person. Removal of reinforcement altogether leads to **extinction**. The process may take a while, however, as you know if you have tried to extinguish a child’s tantrums by withholding your attention. Often the child wins—because you give up ignoring her—and instead of extinction, intermittent reinforcement occurs. This, of course, may encourage even more persistent tantrums in the future.

Antecedents and Behavior Change

In operant conditioning, *antecedents*—the events preceding behaviors—provide information about which behaviors will lead to positive consequences and which will lead to unpleasant ones. Skinner’s pigeons learned to peck for food when a light was on, but not to bother when the light was off, because no food followed pecking when the light was off. In other words, they learned to use the antecedent light as a cue to discriminate the likely consequence of pecking. The pigeons’ pecking was under **stimulus control**—controlled by the discriminative stimulus of the light. This happens in humans too. For example, I found myself (more than once) about to turn into my old office parking lot, even after my department had been relocated to a new building across town. As I drove, the old landmark cues kept me heading automatically to the old office. Another example is the supposedly true story of a getaway car driver in a bank robbery who sped through town, only to be caught by the police when she dutifully stopped at a red light. The stimulus of the red light had come to have automatic control. We all learn to discriminate—to read situations. When should you ask to borrow your roommate’s car—after a major disagreement or after you both have had a great time at a party? Teachers can use cues deliberately in the classroom.

EFFECTIVE INSTRUCTION DELIVERY. One important antecedent to increase positive student responses is the type of instructions you give. Research on **effective instruction delivery (EID)** has found instructions that are concise, clear, and specific, and that communicate an expected result are more effective than vague directions. Statements work better than questions. You should be within a few feet of the students; directions shouted

Antecedents (I, A1) Understand how antecedents can affect learning. Be particularly familiar with the effective uses of cueing.

Extinction The disappearance of a learned response.

Stimulus control Capacity for the presence or absence of antecedents to cause behaviors.

Effective instruction delivery (EID) Instructions that are concise, clear, and specific, and that communicate an expected result. Statements work better than questions.

from across the room are less likely to work. Ideally, you should make eye contact with the students first, and then give the directions (D. S. Roberts, Tingstrom, Olmi, & Bellipanni, 2008).

CUEING. By definition, **cueing** is the act of providing an antecedent stimulus just before a specific behavior is supposed to take place. Cueing is particularly useful in setting the stage for behaviors that must occur at a given time but are easily forgotten. In working with young people, teachers often find themselves correcting behaviors after the fact, asking students, “When are you going to start remembering to . . . ?” These reminders often lead to irritation. The mistake is already made, and the young person is left with only two choices: to promise to try harder or to think, “Why don’t you leave me alone?” Neither response is very satisfying. Presenting a nonjudgmental cue can help prevent such negative confrontations. For example, before a test, an educational psychology instructor might say, “Remember, people often confuse negative (subtraction) reinforcement and punishment. Some of the questions on this exam will test your understanding of the differences.” When students do well on the test, the instructor can reinforce the students’ accomplishments instead of saying, “You still don’t get it. . . .” (Alberto & Troutman, 2017).

What would these principles look like in action? We turn to that next.

Applied Behavior Analysis (I, C4)

When teachers need to change inappropriate or ineffective classroom behaviors that have not changed in response to standard behavioral techniques (e.g., response cost), they often employ applied behavior analysis. Familiarize yourself with the steps in developing and implementing an intervention based on that technique.

PUTTING IT ALL TOGETHER: APPLIED BEHAVIOR ANALYSIS

The behavioral approach to learning has inspired several important contributions to instruction, including systems for specifying learning targets and direct instruction (we will look at these topics in Chapter 14 when we discuss teaching) and class management systems such as group consequences, contingency contracts, and token economies (Landrum & Kauffman, 2006). These approaches are useful when the goal is to learn explicit information or change behaviors and when the material is sequential and factual.

Applied behavior analysis is the application of behavioral learning principles to change behavior in these kinds of situations (Alberto & Troutman, 2017; Kazdin, 2001, 2008).

Ideally, applied behavior analysis requires clear specification of the behavior to be changed; careful measurement of the behavior; analysis of the antecedents and consequences that might be maintaining inappropriate or undesirable behavior; interventions based on behavioral principles to change the behavior; and careful measurement of changes. In research on applied behavior analysis, an ABAB design (described in Chapter 1) is common. That is, researchers take a baseline measurement of the behavior (A), then apply the intervention (B), then stop the intervention to see if the behavior goes back to the baseline level (A), and then reintroduce the intervention (B).

In classrooms, teachers usually cannot follow all the ABAB steps, but they can do the following:

1. Clearly specify the behavior to be changed and the goal. For example, if the student makes “careless” errors in computation, is your goal only one error for every 10 problems? For every 20 problems?
2. Carefully observe and note the current level of the behavior. How many errors per 10 or 20 problems now? What seems to be the reason or cause for the errors? Are there more errors on timed tests? Homework? Group work? Does time of day matter?
3. Plan a specific intervention using antecedents, consequences, or both. For example, offer the student one extra minute of computer time for every problem completed with no computation errors.
4. Keep track of the results, and modify the plan if necessary.

Let’s consider some specific methods for accomplishing step 3—the intervention.

Cueing Providing a stimulus that “sets up” a desired behavior.

Applied behavior analysis The application of behavioral learning principles to understand and change behavior.

Methods for Encouraging Behaviors

As you know, to encourage behavior is to reinforce it. There are several specific ways to encourage existing behaviors or teach new ones. These include teacher attention and praise, the Premack principle, shaping, and positive practice.

REINFORCING WITH TEACHER ATTENTION. Many psychologists advise teachers to “accentuate the positive”—praise students for good behavior, while ignoring misbehavior. Some researchers believe that “the systematic application of praise and attention may be the most powerful motivational and classroom management tool available to teachers” (Alber & Heward, 1997, p. 277; Alber & Heward, 2000). A related strategy is *differential reinforcement*, or ignoring inappropriate behaviors, while being sure to reinforce appropriate behaviors as soon as they occur. For example, if a student is prone to making irrelevant comments (“When is the game this Friday?”), you should ignore the off-task comment, but recognize a task-related contribution as soon as it occurs (Landrum & Kauffman, 2006).

This praise-and-ignore approach can be helpful, but don’t expect it to solve all classroom management problems. Several studies have shown that disruptive behaviors persist when teachers use positive consequences (mostly praise) as their *only* classroom management strategy (McGoey & DuPaul, 2000; Pfiffner & O’Leary, 1987; Sullivan & O’Leary, 1990). Also, if attention from other students is reinforcing the problem behaviors, the teacher’s ignoring them won’t help much.

There is a second consideration in using praise. Merely “handing out compliments” will not improve behavior. To be effective, praise must (1) be contingent on the behavior to be reinforced, (2) specify clearly the behavior being reinforced, and (3) be believable (Landrum & Kauffman, 2006; O’Leary & O’Leary, 1977). In other words, the praise should be sincere recognition of a well-defined behavior so students understand what they did to warrant the recognition. In addition, some evidence indicates that praising students for being intelligent when they succeed can undermine their motivation if they do not perform as well the next time. When that happens, students who had been praised for being smart may be less persistent and enjoy the task less compared to students who had been praised earlier for working hard (Mueller & Dweck, 1998). Finally, some psychologists have suggested that teachers’ use of praise tends to focus students on learning to win the teacher’s approval rather than on learning for its own sake. Perhaps the best advice is to be aware of the potential dangers of the overuse or misuse of praise and navigate accordingly. The *Guidelines: Applying Operant Conditioning—Using Praise Appropriately* on page 302 give ideas for using praise effectively, based on Brophy’s (1981) extensive review of the subject and Alan Kazdin’s (2008) work with parents and teachers.

SELECTING REINFORCERS: THE PREMACK PRINCIPLE. In most classrooms, many reinforcers are readily available, such as the chance to talk to other students, work at computers, have free time, get homework or test exemptions, select your own seat, lead the line, be the teacher’s assistant, or feed the class animals. However, teachers tend to offer these opportunities in a rather haphazard way. Just as with praise, by making privileges and rewards directly contingent on learning and positive behavior, the teacher can greatly increase both learning and desired behavior.

A helpful guide for choosing the most effective reinforcers is the **Premack principle**, named for David Premack (1965). According to the Premack principle, a preferred activity can be an effective reinforcer for a less-preferred activity. This is sometimes referred to as “Grandma’s rule”: First, do what I want you to do, and then you may do what you want to do. Elizabeth used this principle in her class when she told them they could work together on their Civil War news program after they had quietly completed the first section of the worksheet on their own.

If students didn’t have to study, what would they do? The answers to this question may suggest many possible reinforcers. For most students, talking, moving around the room, sitting near a friend, being exempt from assignments or tests, editing the class Web page, using the computer, making a video, or playing games are preferred activities. The best way to determine appropriate reinforcers for your students may be to watch

MyLab Education
Video Example 7.2

In this special education class, students earn “money” for appropriate behaviors, which they can then spend in an auction. The money and the teacher’s praise are reinforcers. The auction items are incentives.

Premack principle

Principle stating that a more-preferred activity can serve as a reinforcer for a less-preferred activity.

GUIDELINES

Applying Operant Conditioning: Using Praise Appropriately

Be clear and systematic in giving praise.

Examples

1. Make sure praise is tied directly to appropriate behavior.
2. Make sure the student understands the specific action or accomplishment that is being praised. Say, "I am impressed that you made sure everyone in your group got a chance to speak," not, "Good job leading the group."

Make praise "appreciative" not "evaluative" (Ginott, 1972).

Examples

1. Praise and appreciate the student's efforts, accomplishments, and actions—especially when the actions help others.
2. Don't evaluate the student's character or personality—praise the action, not the person.

Set standards for praise based on individual abilities and limitations.

Examples

1. Praise progress or accomplishment in relation to the individual student's past efforts.
2. Focus the student's attention on his or her own progress, not on comparisons with others.

Attribute the student's success to effort and ability so the student will gain confidence that success is possible again.

Examples

1. Don't imply that the success may be based on luck, extra help, or easy material.

2. Ask students to describe the problems they encountered and how they solved them.

Make praise really reinforcing.

Examples

1. Don't attempt to influence the rest of the class by singling out some students for praise. This tactic frequently backfires, because students know what's really going on. In addition, you risk embarrassing the student you have chosen to praise.
2. Don't give undeserved praise to students simply to balance failures. It is seldom consoling and calls attention to the student's inability to earn genuine recognition.
3. Don't use "caboozing"—tacking a criticism on at the end, as in "Good job on completing your homework this week. Why can't you do that every week?" (Kazdin, 2008).

Recognize genuine accomplishments.

Examples

1. Reward the attainment of specified goals, not just participation.
2. Do not reward uninvolved students just for being quiet and not disrupting the class.
3. Tie praise to students' improving competence or to the value of their accomplishment. Say, "I noticed that you double-checked all your problems. Your score reflects your careful work."

For more information on teacher praise, see interventioncentral.org/home and search for "teacher praise."

what they do in their free time. (For more ideas, see <http://www.interventioncentral.org/> and search for "rewards")

For the Premack principle to be effective, the less-preferred behavior must happen first. In the following dialogue, observe how the teacher loses a perfect opportunity to use the Premack principle:

Students: Oh, no! Do we have to work on grammar again today? The other classes got to discuss the play we saw in the auditorium this morning.

Teacher: But the other classes finished the lesson on sentences yesterday. We're almost finished too. If we don't finish the lesson, I'm afraid you'll forget the rules we reviewed yesterday.

Students: Why don't we finish the sentences at the end of the period and talk about the play now?

Teacher: Okay, if you promise to complete the sentences later.

Discussing the play could have served as a reinforcer for completing the lesson. As it is, the class may well spend the entire period discussing the play. Just as the discussion becomes fascinating, the teacher will have to end it and insist that the class return to the grammar lesson.

Connect and Extend to PRAXIS II®

Encouraging/Discouraging Behaviors (I, B2)

Understand the appropriate uses of techniques to encourage or discourage various classroom behaviors. Know the limitations and problems associated with these types of interventions.

SHAPING. What happens when students continually fail to gain reinforcement because they simply cannot perform a skill in the first place? Consider these examples:

- A fourth-grade student looks at the results of the latest mathematics test. “No credit on almost half of the problems again because I made one dumb mistake in each problem. I hate math!”
- A tenth-grade student finds some excuse each day for avoiding the softball game in gym class. The student cannot catch a ball and now refuses to try.

In both situations, the students are receiving no reinforcement for their work because the end product of their efforts is not good enough. A safe prediction is that the students will soon learn to dislike the class, the subject, and perhaps the teacher and school in general. One way to prevent this problem is the strategy of **shaping**, also called **successive approximations**. Shaping involves reinforcing progress instead of waiting for perfection.

To use shaping, the teacher must take the final complex behavior the student is expected to master and break it down into a number of small, manageable steps—bite-size pieces. One approach that identifies the small steps is **task analysis**, originally developed by R. B. Miller (1962) to help the armed services train personnel. Miller's system begins with a definition of the final performance requirement—what the trainee (or student) must be able to do at the end of the program or unit. Then, the steps that will lead to the final goal are specified. The procedure simply breaks skills and processes down into subskills and subprocesses—small steps to success.

Consider an example of task analysis in which students must write a position paper based on research. If the teacher assigned the position paper without analyzing the task, what could happen? Some of the students might not know how to do systematic computer research. They might read one or two entries in Wikipedia and then write about their position based only on this brief reading. Another group of students might know how to use search engines to do research online and how to find information from indexes in books but have difficulty integrating information to reach conclusions. They might hand in lengthy papers listing summaries of different ideas without any synthesis or conclusions. Another group of students might be able to draw conclusions, but their written presentations might be so confusing and grammatically incorrect that the teacher could not understand what they were trying to say. Each of the groups would have failed to fulfill the assignment, but for different reasons.

A task analysis presents the logical sequence of steps leading toward the final goal. An awareness of this sequence can help teachers make sure that students have the necessary skills before they move to the next step. In addition, when students have difficulty, the teacher can pinpoint problem areas. Many behaviors can be improved through shaping, especially the acquisition of skills that involve persistence, endurance, increased accuracy, greater speed, or extensive practice to master. Because shaping is a time-consuming process, however, it should not be used if success can be attained through simpler methods such as cueing.

POSITIVE PRACTICE. In **positive practice**, students replace one behavior with another. This approach is especially appropriate for dealing with academic errors. When students make a mistake, they must correct it as soon as possible and practice the correct response. The same principle can be applied when students break classroom rules. Instead of being punished, the student might be required to practice the correct alternative action; for example, entering the room and immediately putting backpacks in assigned places. This process sometimes is called *positive practice overcorrection* because the correct behavior is practiced until it becomes almost automatic (G. A. Cole, Montgomery, Wilson, & Milan, 2000; Marvin, Rapp, Stenske, Rojas, Swanson, & Bartlett, 2010). The *Guidelines: Applying Operant Conditioning—Encouraging Positive Behaviors* on the next page summarize different ways of encouraging positive behaviors.

Remember, there is one element that is part of every behavioral learning program—specific practice of correct behaviors. Contrary to popular wisdom, practice does not

Shaping Reinforcing each small step of progress toward a desired goal or behavior.

Successive approximations Reinforcing small steps to reach a goal; the small component steps that make up a complex behavior.

Task analysis System for breaking down a task hierarchically into basic skills and subskills.

Positive practice Practicing correct responses immediately after errors.

GUIDELINES

Applying Operant Conditioning: Encouraging Positive Behaviors

Make sure you recognize positive behavior in ways that students value.

Examples

1. When presenting class rules, set up positive consequences for following rules as well as negative consequences for breaking rules.
2. Recognize honest admissions of mistakes by giving a second chance: "Because you admitted that you copied your paper from a book, I'm giving you a chance to rewrite it."
3. Offer desired rewards for academic efforts, such as extra recess time, exemptions from homework or tests, or extra credit on major projects.

When students are tackling new material or trying new skills, give plenty of reinforcement.

Examples

1. Find and comment on something good in every student's first life drawing.
2. Reinforce students for encouraging each other. "French pronunciation is difficult and awkward at first. Let's help each other by eliminating all giggles when someone is brave enough to attempt a new word."

After new behaviors are established, give reinforcement on an unpredictable schedule to encourage persistence.

Examples

1. Offer surprise rewards for good participation in class.
2. Start classes with a short, written extra-credit question. Students don't have to answer, but a good answer will add points to their total for the semester.
3. Make sure the good students get compliments for their work from time to time. Don't take them for granted.

Use the Premack principle to identify effective reinforcers.

Examples

1. Watch what students do with their free time.
2. Notice which students like to work together. The chance to work with friends is often a good reinforcer.

Use cueing to help establish new behaviors.

Examples

1. Put up humorous signs in the classroom to remind students of rules.
2. At the beginning of the year, as students enter class, call their attention to a chart posted on the board listing all of the materials they should have with them when they come to class.

Make sure all students, even those who often cause problems, receive some praise, privileges, or other rewards when they do something well.

Examples

1. Review your class list occasionally to make sure all students are receiving some reinforcement.
2. Set standards for reinforcement so that all students will have a chance to be rewarded.
3. Check your biases. Are boys getting more opportunities for reinforcement than girls, or vice versa? How about students of different races?

Establish a variety of reinforcers.

Examples

1. Let students suggest their own reinforcers or choose from a "menu" of reinforcers with "weekly specials."
2. Talk to other teachers or parents about ideas for reinforcers.

make perfect. Instead, practice makes *permanent* the behaviors practiced, so practicing accurate behaviors is important.

Contingency Contracts, Token Reinforcement, and Group Consequences

You've just learned about ways to incorporate positive reinforcement, the Premack principle, shaping, and positive practice into your classroom management system. As other examples of effective classroom management, consider contingency contracts, token reinforcement, and group consequences.

Contingency contract A contract between the teacher and a student specifying what the student must do to earn a particular reward or privilege.

CONTINGENCY CONTRACTS. In a contingency contract program, the teacher draws up an individual contract with each student, describing exactly what the student must do to earn a particular privilege or reward. In some programs, students suggest behaviors to be reinforced and the rewards that can be gained. The negotiating process itself can be an educational experience, as students learn to set reasonable goals and abide by the terms of a contract. And, if students participate in setting the goals, they often are more

A BASIC CONTINGENCY CONTRACT

An example contract for older students. This can be adapted to fit the situation and needs of the student.

Contract

I, _____, declare on this date _____
that I agree to do the following:

Goals:

1.
2.
3.

These goals will be considered complete if and when _____

Rewards If Goals are Met:

1.
2.
3.

Consequences if Goals are Not Met:

1.
2.
3.

This contract will be reviewed by the student and teacher on the following date:
_____.

By signing this contract all parties agree to the stipulations in the document and will following accordingly.

(Signature of Student)

(Date)

(Signature of Teacher)

(Date)

committed to reaching them (Locke & Latham, 2002; Schunk, 2016; Schunk, Meece, & Pintrich, 2014).

An example of a contract for completing assignments that is appropriate for intermediate and upper-grade students is presented in Figure 7.2. This contract should state clear goals, criteria to determine if the goals are met adequately and completely, and consequences for success or failure in reaching the goals. An important part of the agreement is a specified time to review the contract to be sure the terms are clear and helpful and perhaps to make adjustments. Information about progress can support student motivation.

TOKEN REINFORCEMENT SYSTEMS.

STOP & THINK Have you ever participated in a program where you earned points or credits that you could exchange for a reward? Are you a member of a frequent flyer club, or do you get points on your credit card? Do you get one free coffee for every 10 coffee purchases or

a free smoothie when you fill a punch card? Does being a part of such a program affect your buying habits? How? I know I pay for everything I can with one credit card to get the points and always try to fly on one airline for the same reason. I am participating in a token reinforcement system. •

Often, it is difficult to provide positive consequences quickly for all the students who deserve them. A **token reinforcement system** can help solve this problem by allowing all students to earn tokens for both academic work and positive classroom behavior. The tokens may be points, checks, holes punched in a card, chips, play money, or anything else that is easily identified as the student's property. Periodically, the students exchange the tokens they have earned for some desired reward (Alberto & Troutman, 2017; Kazdin, 2001).

Depending on the age of the student, the rewards could be small toys, school supplies, free time, special class jobs, positive notes sent home, time to listen to music or play computer games, a chance to sit with friends, or other privileges. When a "token economy," as this kind of system is called, is first established, the tokens should be given out on a fairly continuous schedule, with chances to exchange the tokens for rewards available early and often. Once the system is working well, however, tokens should be distributed on an intermittent schedule and saved for longer periods of time before they are exchanged for rewards.

Another variation is to allow students to earn tokens in the classroom and then exchange them for rewards at home. These plans are very successful when parents are willing to cooperate. Usually a note or report form is sent home daily or twice a week. The note indicates the number of points earned in the preceding time period. The points may be exchanged for minutes of television or videogame time, access to special toys, or private time with parents. Points can also be saved up for larger rewards such as trips. Do not use this procedure, however, if you suspect the child might be pressured for perfection or punished for poor reports (Jurbergs, Palcic, & Kelly, 2007).

Token reinforcement systems are complicated and time-consuming. Generally, they should be used in only three situations: (1) to motivate students who are completely uninterested in their work and have not responded to other approaches; (2) to encourage students who have consistently failed to make academic progress; and (3) to deal with a class that is out of control. Some groups of students seem to benefit from token economies more than others. Students with intellectual disabilities, children who have failed often, students with few academic skills, and students with behavior problems all seem to respond to the concrete, direct nature of token reinforcement.

The few pages devoted here to token reinforcement and contingency contracts can offer only an introduction to these programs. If you want to set up a large-scale reward program in your classroom, you should probably seek professional advice. Often, the school psychologist, counselor, or principal can help.

GROUP CONSEQUENCES. A teacher can base reinforcement for the class on the behavior of selected target students (e.g., "If Jamarcus, Evan, and Mei stay on their mats until the end of nap time, then we will have a special snack"). Also, the class can earn rewards based on the collective behavior of everyone in the class, usually by adding each student's points to a class or a team total.

PUT YOURSELF IN HIS PLACE Imagine you are a very bright third-grade student in a small, Texas town. You are an amazing mimic and love to tell jokes. Because you are pretty bored at times with the pace of class, you would rather have fun than focus on the lessons, so you can cause trouble. What does our clever teacher do? She tells you and the class that if everyone works hard all week, then you can do your stand-up comedy routine for the class every Friday afternoon. What was a problem becomes a solution and Jamie Foxx begins his career as a master entertainer. (To hear Jamie Foxx tell the story, listen to this podcast <http://fourhourworkweek.com/2015/12/06/jamie-foxx/>) •

MyLab Education Video Example 7.3

In this class, students receive paper raindrops when they achieve a perfect score on an assignment. How is this system similar to and different from the token reinforcement systems described here?

Token reinforcement system System in which tokens earned for academic work and positive classroom behavior can be exchanged for some desired reward.

The teacher in the *Put Yourself in His Place* is using a combination of individual (for Jamie) and group (for the class) consequences—and expanding the learning time for everyone in the process.

The **good behavior game** is a more structured example of group consequences. Teachers and students discuss what would make the classroom a better place and identify behaviors that get in the way of learning. Based on this discussion, class rules are developed and the class is divided into two or three teams. Each time a student breaks one of the rules, that student's team is given a mark. The team with the fewest marks at the end of the period receives a special reward or privilege (longer recess, first to lunch, the team "spaceship" is moved closer to the "moon," and so on). If all teams earn fewer than a preestablished number of marks, all receive the reward. Sometimes a class needs a "no tattling" rule so the teams don't spend all their time pointing out each other's mistakes. Most studies indicate that even though the game generates only small improvements in academic achievement, it can produce definite improvements in the behaviors listed in the good behavior rules, and it can prevent many behavior problems, especially in classes with frequent issues. One important aspect of the program is to be sure the rewards available are attractive and valued. If you use the good behavior game, you might survey your students first to identify their preferences for rewards (Flower, McKenna, Bunuan, Muething, & Vega, 2014; Tingstrom, Sterling-Turner, & Wilczynski, 2006).

What happens if we add interventions that target academic achievement to the proven power of the good behavior game? Catherine Bradshaw and her colleagues did just that (Bradshaw, Zmuda, Kellam, & Ialongo, 2009). They followed 678 mostly African American students from urban first-grade classes through their high school years. In first grade these students participated in either a control group or one of two specific programs: (a) a classroom-centered intervention that combined the good behavior game with an enhanced academic curriculum (read-alouds, journal writing, Reader's Theater, critical thinking skills, Mimosa math, small-group activities, etc.) or (b) a family-centered intervention that promoted parent involvement in home reading and math activities and helped parents develop better child management strategies. Students who participated in the classroom intervention that combined the good behavior game with an enhanced academic curriculum in first grade had higher scores on standardized achievement tests in grade 12, reduced referrals for special education services, higher rates of high school graduation, and higher rates of college attendance *12 years later!* The parent involvement program had a small significant effect on only reading test scores. So early investment in helping students learn positive behaviors *and* academic skills can make a difference for years to come.

You can also use **group consequences** without dividing the class into teams; that is, you can base reinforcement on the behavior of the whole class. However, caution is needed using group approaches—the whole group should not suffer for the misbehavior or mistakes of one individual if the group has no real influence over that person. I once saw an entire class break into cheers when the teacher announced that one boy was transferring to another school. The chant "No more points! No more points!" filled the room. The "points" referred to the teacher's system of giving one point to the whole class each time anyone broke a rule. Every point meant 5 minutes of recess lost. The boy who was transferring had been responsible for the loss of many recess periods. He was not very popular to begin with, and the point system, though quite effective in maintaining order, had made the boy an outcast in his own class.

Peer pressure in the form of support and encouragement, however, can be a positive influence. Group consequences are recommended when students care about the approval of their peers (Theodore, Bray, Kehle, & Jenson, 2001). If the misbehavior of several students seems to be encouraged by the attention and laughter of other students, then group consequences could be helpful. Teachers might show students how to give support and constructive feedback to classmates. If a few students seem to enjoy sabotaging the system, those students may need separate arrangements such as putting all the saboteurs together in their own group.

Good behavior game

Arrangement where a class is divided into teams and each team receives demerit points for breaking agreed-upon rules of good behavior.

Group consequences

Rewards or punishments given to a class as a whole for adhering to or violating rules of conduct.

Handling Undesirable Behavior

Before we explore ways to handle problem behaviors, let's take a minute to consider why students disrupt class or break rules. We saw one reason in the story about Jamie Foxx—he was just bored and also was a great entertainer. How much more rewarding it must have been for a third grader to enjoy the laughter of his friends than to focus on a lesson he already understood. Other possibilities—perhaps a student has an unidentified learning disability or lacks the social skills to make friends and disrupts as a way to vent frustration or get attention. Maybe the student feels no connection with the lessons because her race or ethnicity is seldom represented in the materials or the teacher seems have low expectations for her. What is behind the misbehavior? Are your teaching methods and materials are right for the students? Sometimes, class disruptions or lack of motivation indicate that teaching practices need to be changed. Maybe the class rules are unclear or are enforced inconsistently. Perhaps your instructions are vague. Maybe the text is too easy or too hard or the pace is wrong. If these problems exist, rewards or punishments may improve the situation temporarily, but the students will still have trouble learning the academic material. *Improve your teaching first.* Focus on the positive, develop caring and respectful relationships with your students, keep the pace and difficulty level right, and design engaging, culturally appropriate lessons and assignments.

Assume you have addressed all these issues pretty well, but some problems persist—now what? There are times when you must cope with undesirable behavior, either because other methods fail or because the behavior itself is dangerous and calls for direct action. For this purpose, negative reinforcement, reprimands, response cost, and social isolation all offer possible solutions.

NEGATIVE REINFORCEMENT. Recall the basic principle of negative reinforcement: If an action stops or avoids something unpleasant, then that action is likely to occur again in similar situations. Negative reinforcement was operating in Elizabeth's classroom. When they moaned and complained, her students escaped the test, so negative reinforcement probably increased the frequency of complaining in the future.

Negative reinforcement can also be used to enhance learning. To do this, you place students in mildly unpleasant situations so they can “escape” when their behavior improves. Consider these examples:

Teacher to a third-grade class: “When the supplies are put back in the cabinet and each of you is sitting quietly, we will go outside. Until then, we will miss our recess.”

High school teacher to a student who seldom finishes in-class assignments: “As soon as you complete the assignment, you may join the class in the auditorium. But until you finish, you must work in the study hall.”

Antonio Banderas in the film “Take the Lead”: Working with a group of totally uncooperative high school students, Banderas blasts the students with “oldies” music they hate, only turning it off when the entire class is lined up and ready to practice their ballroom dance moves.

You may wonder why these negative reinforcement examples are not considered punishment. Surely, staying in during recess, not accompanying the class to a special program, or being subjected to music you hate is punishing. But the focus in each case is on *strengthening* specific behaviors (putting away supplies, finishing in-class assignments, lining up and cooperating with the teacher). The teacher strengthens (reinforces) the behaviors by removing something aversive *as soon as the desired behaviors occur*. Because the consequence involves removing or “subtracting” a stimulus, the reinforcement is negative.

Negative reinforcement also gives students a chance to exercise control. Missing recess or hearing music you hate are unpleasant situations, but in each case, the students retain control. As soon as they perform the appropriate behavior, the unpleasant situation ends. In contrast, punishment occurs after the fact, and a student cannot so easily control or terminate it.

There are several rules for negative reinforcement: Describe the desired change in a positive way. Don't bluff. Make sure you can enforce your unpleasant situation. Follow through despite complaints. Insist on action, not promises. If the unpleasant situation terminates when students *promise* to be better next time, you have reinforced making promises, not making changes (Alberto & Troutman, 2017; O'Leary, 1995).

REPRIMANDS. In the *Junction Journal*, my daughter's elementary school newspaper, I read the following lines in a story called "Why I Like School," written by a fourth-grader: "I also like my teacher. She helps me understand and learn. She is nice to everyone. I like it when she gets mad at somebody, but she doesn't yell at them in front of the class, but speaks to them privately."

Soft, calm, private **reprimands** are more effective than loud, public reprimands in decreasing disruptive behavior (Landrum & Kauffman, 2006). Research has shown that when reprimands are loud enough for the entire class to hear, disruptions increase or continue at a constant level. Some students enjoy public recognition for misbehavior, or they don't want classmates to see them "lose" to the teacher. If they are not used too often, and if the classroom is generally a positive, warm environment, then students usually respond quickly to private reprimands (J. S. Kaplan, 1991).

RESPONSE COST. The concept of **response cost** is familiar to anyone who has ever paid a fine. For certain infractions of the rules, people must lose some reinforcer—money, time, privileges (J. E. Walker, Shea, & Bauer, 2004). In a class, the concept of response cost can be applied in a number of ways. The first time a student breaks a class rule, the teacher gives a warning. The second time, the teacher makes a mark beside the student's name in the grade book. The student loses 2 minutes of recess for each mark accumulated. For older students, a certain number of marks might mean losing the privilege of working in a group or using the computer.

SOCIAL ISOLATION. One of the most controversial behavioral methods for decreasing undesirable behavior is the strategy of **social isolation**, often called **time out** from reinforcement. The process involves removing a highly disruptive student from the classroom for 5 to 10 minutes. The student is placed in an empty, uninteresting space alone—the punishment is brief isolation from other people. A trip to the principal's office or confinement to a chair in the corner of the general classroom does not have the same effect as sitting alone in an empty place. But beware. If a brief time out does not help improve the situation, don't try a longer time out. Alan Kazdin (2008), who has been helping teachers and parents work positively with children for decades, says, "If you are giving longer and longer time-outs, it means your strategy is failing. The answer is not to escalate—just the opposite in fact. If you are giving more and longer time-outs, this should tell you that you need to do more to positively reinforce good behaviors to replace the unwanted behaviors" (p. 10)—good advice for any form of punishment.

SOME CAUTIONS ABOUT PUNISHMENT. Remember the "no more points" chant I described under group consequences? The teacher actually was using a punishment-based system—*removal punishment* to be exact. For every rule-breaking point, the class had 5 minutes of recess removed. The system led to rejection of the main rule breaker.

Unfortunately, punishment seems to be a very common part of parenting and schooling. I say *unfortunately* because study after study shows that punishment by itself, as usually practiced in homes and schools, just doesn't work. It tells children what to stop doing (often, they knew that already), but it does not teach them what to do instead (Kazdin, 2008). Whenever you consider the use of punishment, you should make it part of a two-pronged attack. The first goal is to carry out the punishment and suppress the undesirable behavior. The second goal is to make clear what the student should be doing instead and to provide reinforcement for those desirable actions. Thus, while the problem behaviors are being suppressed, positive alternative responses are being strengthened. As you will see in the next section, recent approaches really emphasize

Reprimands Criticisms for misbehavior; rebukes.

Response cost Punishment by loss of reinforcers.

Social isolation Removal of a disruptive student for 5 to 10 minutes.

Time out Technically, the removal of all reinforcement. In practice, isolation of a student from the rest of the class for a brief time.

GUIDELINES

Applying Operant Conditioning: Using Punishment

Try to structure the situation so you can use negative reinforcement rather than punishment.

Examples

1. Allow students to escape unpleasant situations (completing additional workbook assignments, weekly tests of math facts) when they reach a level of competence.
2. Insist on actions, not promises. Don't let students convince you to change the terms of the agreement.

If you do use punishment, keep it mild and brief—then pair it with doing the right thing.

Examples

1. Time out for young children—no more than 2 to 5 minutes; loss of points—no more than 1 sticker if the student can earn 5 in a day (Kazdin, 2008).
2. Pair the brief, mild punishment with reinforcement for doing the right thing or restitution. If a student writes graffiti in the restroom, use brief punishment plus cleaning off the graffiti.

Be consistent in your application of punishment.

Examples

1. Avoid inadvertently reinforcing the behavior you are trying to punish. Keep confrontations private, so that students don't become heroes for standing up to the teacher in a public showdown.
2. Let students know in advance the consequences of breaking the rules by posting major class rules for younger students or outlining rules and consequences in a course syllabus for older students.
3. Tell students they will receive only one warning before punishment is given. Give the warning in a calm way, and then follow through.
4. Make punishment as unavoidable and immediate as is reasonably possible.
5. Don't punish when you are angry—you may be too harsh, then need to take it back later—which shows a lack of consistency.

Focus on the students' actions, not on the students' personal qualities.

Examples

1. Reprimand in a calm but firm voice.
2. Avoid vindictive or sarcastic words or tones of voice. You might hear your own angry words later when students imitate your sarcasm.
3. Stress the need to end the problem behavior instead of expressing any dislike you might feel for the student.
4. Be aware that students of color are disproportionately punished, sent to detention, and expelled from school. Are your policies fair?

Adapt the punishment to the infraction.

Examples

1. Ignore minor misbehaviors that do not disrupt the class, or stop these misbehaviors with a disapproving glance or a move toward the student.
2. Make sure the punishment isn't worse than the crime—don't take away all the free time a student has earned for one infraction of the rules, for example (Landrum & Kauffman, 2006). Less punishment is more effective, as long as it is paired with reinforcement for doing the right thing.
3. Don't use extra homework as a punishment for misbehaviors such as talking in class.
4. When a student misbehaves to gain peer acceptance, removal from the group of friends can be effective, because this is really time out from a reinforcing situation.
5. If the problem behaviors continue, analyze the situation and try a new approach. Your punishment may not be very punishing, or you may be inadvertently reinforcing the misbehavior.

For more information on punishment, see interventioncentral.org and search for "punishment."

supporting positive behaviors. The *Guidelines: Applying Operant Conditioning—Using Punishment* give ideas for using punishment for positive purposes.

I'll repeat: Punishment in and of itself does not lead to any positive behavior. Harsh punishment communicates to students that "might makes right" and may encourage retaliation. In addition, punishment works best when the potential punisher—the teacher—is around. Students learn to "be good" when the teacher is in the room, but when the teacher leaves or there is a substitute teacher, the system might fall apart. Punishment tends to focus students on the consequences of their actions for themselves instead of challenging them to think about the impact of their behavior on others; as a result punishment does not instill compassion or empathy for others. Finally, punishment can interfere with developing a caring relationship with your students (Alberto & Troutman, 2017; Hardin, 2008; Kohn, 2005; J. E. Walker et al., 2004).

Reaching Every Student: Severe Behavior Problems

Students with severe behavior problems provide some of the most difficult challenges for teachers. Two studies show how applied behavioral principles can be useful in helping these students.

Lea Theodore and her colleagues (2001) worked with the teacher of five adolescent males who were diagnosed as having severe emotional disorders. A short list of clear rules was established (e.g., use no obscene words, comply with the teacher's requests within 5 seconds, make no verbal putdowns). The rules were written on index cards taped to each student's desk. The teacher had a checklist on his desk with each student's name to note any rule breaking. This checklist was easily observable, so students could monitor their own and each other's performance. At the end of the 45-minute period, a student chose a "criterion" from a jar. The possible criteria were performance of the whole group, student with the highest score, student with the lowest score, the average of all students, or a random single student. If the student or students selected to be the criterion had five checks or fewer for rule breaking, then the whole group got a reward, also chosen randomly from a jar. The possible rewards were things like a power drink, a bag of chips, a candy bar, or a late-to-class pass. An ABAB design was used—baseline, 2-week intervention, 2-week withdrawal of intervention, and 2-week return to group consequences. All students showed clear improvement in following the rules when the reward system was in place. Students liked the approach, and the teacher found it easy to implement.

Behavioral interventions are often used with children with autism (see S. M. Bartlett, Rapp, Krueger, & Henrickson, 2011; L. J. Hall, Grundon, Pope, & Romero, 2010; Soares, Vannest, & Harrison, 2009). For example, Sara Bartlett and her colleagues tested a *response cost* strategy to treat Evan, an 8-year-old boy with autism who had very limited verbal abilities and a problem with spitting. The researchers let the boy listen to a radio, identified as a favorite toy by his teachers, as he worked at a table in a therapy room in his school. When the boy spit, the radio was removed for 10 seconds, and then replaced. Evan's spitting went to near zero rates during these training sessions. Then the researchers stopped the response cost strategy and the radio was not removed when Evan spit. The rates of spitting went back up. Next the researchers reinstituted the response cost, removing the radio for 10 seconds, and Evan's spitting went back down again to near zero. (Notice this also is an example of an ABAB research design—baseline, treatment, return to baseline, reinstate treatment.) The researchers moved Evan back into the classroom and conducted his training sessions there. Finally they taught Evan's teachers to use the strategy and Evan's spitting stayed at near zero in his general education classroom through the entire 4-month follow-up period.

Teaching and Management
(I, A1; II, A3; I, C4)
Identify major approaches to teaching and classroom management that are based on behavioral principles. Understand the advantages and disadvantages of each.

CURRENT APPLICATIONS: FUNCTIONAL BEHAVIORAL ASSESSMENT, POSITIVE BEHAVIOR SUPPORTS, AND SELF-MANAGEMENT

Earlier in this chapter when we discussed coping with problem behaviors, I cautioned you to first ask "why"—why is the student disrupting the class or acting out? Teachers in both general and special education classes have had success with a new approach that begins by asking a similar question, "What are students getting out of their problem behaviors—what functions do these behaviors serve?" The focus is on the *why* of the behavior, not on the *what* (Lane, Falk, & Wehby, 2006; Lane, Stage et al., 2008; Warren et al., 2006).

The reasons for problem behaviors generally fall into four categories (Barnhill, 2005). Students act out to:

1. Receive attention from others—teachers, parents, or peers.
2. Escape from some unpleasant situation—an academic or social demand.
3. Get a desired item or activity.
4. Meet sensory needs, such as stimulation from rocking or flapping arms for some children with autism.

If the reason for the behavior is known, then the teacher can devise ways of supporting positive behaviors that will serve the same “why” function. For example, I once worked with a middle school principal who was concerned about a boy who had lost his father a few years earlier and was having trouble in a number of subjects, especially math. The student disrupted math class at least twice a week and ended up in the principal’s office. There, the boy enjoyed the principal’s undivided attention. After a scolding, they talked about sports because the principal liked the student and was concerned that he had no male role models. It is easy to spot the function of the classroom disruptions—they always led to (1) escape from math class (negative reinforcement) and (2) one-on-one time with the principal (positive reinforcement after a little bit of reprimanding). The principal, teacher, and I developed a way to support the student’s positive behaviors in math by getting him some extra tutoring and by giving him time with the principal when he completed math problems instead of when he acted up in class. The new positive behaviors served many of the same functions as the old problem behaviors.

Discovering the “Why”: Functional Behavioral Assessments

The process of understanding the “why” of a problem behavior is known as **functional behavioral assessment (FBA)**. Using a wide range of procedures to map the A–B–Cs of the situation (antecedents–behaviors–consequences), teachers try to identify the reason for the behavior (Barnhill, 2005). Figure 7.3 summarizes the possible functions of many school behaviors.

Many different procedures might help you determine the functions of a specific behavior in your classes. You can begin by interviewing students about their behaviors. In one study, students were asked to describe what they did that got them in trouble in school, what happened just before they acted out, and what happened right after. Even though the students were not always sure why they acted out, they seemed to benefit from talking to a concerned adult who was trying to understand their situation, not just reprimand them (S. G. Murdock, O’Neill, & Cunningham, 2005). But you will need to do more than just talk to students. You might also talk to parents or other teachers. You could conduct an A–B–C observation with these questions in mind: When and where does the problem behavior occur? What people or activities are involved? What happens right before—what do others do or say, and what did the target student do or say? What happens right after the behavior—what did you, other students, or the target student do or say? What does the target student gain or escape from by engaging in the behavior—what changes after the student acts out? A more structured approach is shown in Figure 7.4 on page 314, an observation guide for FBA based on a simple A–B–C analysis. Using this information, the teacher found out that the student acted out whenever the class was transitioning to another activity. The sources of reinforcement for the student are clear too.

The same behaviors may serve different functions for different students. For example, an FBA of three preschool students found that two of the students were aggressive and uncooperative in order to gain the teacher’s attention, but the third child actually was trying to escape or avoid teacher attention (Dufrene, Doggett, Henington, & Watson, 2007). With information from an FBA, teachers developed an intervention package, including *positive behavior supports (PBS)* for each child. Two students met specific standards to get the teacher attention they wanted, but the third child got to be “left alone” as long as he met certain standards.

Functional behavioral assessment (FBA)

Procedures used to obtain information about antecedents, behaviors, and consequences to determine the reason or function of the behavior.

FIGURE 7.3

THE POSSIBLE FUNCTIONS AND CONSEQUENCES THAT MAINTAIN SOME TROUBLING BEHAVIORS

Functions of Behavior	Maintaining Consequences
<u>To gain attention:</u> Social from adult (teacher, parent, paraeducator, customer, etc.) Social from peer	<u>Positive Reinforcement</u> Receiving attention increases the future rate or probability of the student engaging in the behavior again.
<u>To gain a tangible:</u> Assistance in getting: Object Activity Event	<u>Positive Reinforcement</u> Receiving the tangible increases the future rate or probability of the student engaging in the behavior again.
<u>To gain sensory stimulations:</u> Visual Gustatory Auditory Kinesthetic Olfactory Proprioceptive	<u>Positive Automatic Reinforcement</u> Provision of the sensory input by engaging in the behavior itself increases the future rate or probability of the student engaging in the behavior again.
<u>To escape from attention:</u> Attention from peer or adult Social interaction with peer	<u>Negative Reinforcement</u> Removing the student from the interaction that is aversive increases the future rate or probability of the behavior.
<u>To escape from:</u> Demanding or boring task Setting, activity, event	<u>Negative Reinforcement</u> Removing the stimulus the student finds aversive increases the future rate or probability of the behavior.
<u>To escape from sensory stimulation:</u> Internal stimulation that is painful or discomforting	<u>Negative Automatic Reinforcement</u> Attenuation of painful or discomforting internal stimulation by engaging in the behavior itself increases the future rate and/or probability of the student engaging in the behavior again.

Positive Behavior Supports

The Individuals with Disabilities Education Act (IDEA, 2004) discussed in Chapter 4 requires positive behavior supports for students with disabilities and those at risk for special education placement. **Positive behavior supports (PBS)** are the actual interventions designed to replace problem behaviors with new actions that serve the same purpose for the student.

Positive behavior supports can help students with disabilities succeed in inclusion classrooms. For example, the disruptive behavior of a 5-year-old boy with an intellectual disability was nearly eliminated in a relatively short time through a PBS intervention that was based on an FBA conducted by the general education teaching staff and the special education teacher. The intervention included making sure the tasks assigned were at the

Positive behavior supports (PBS) Interventions designed to replace problem behaviors with new actions that serve the same purpose for the student.

FIGURE 7.4

A SIMPLE STRUCTURED OBSERVATION GUIDE FOR FUNCTIONAL BEHAVIORAL ASSESSMENT USING THE A-B-C FRAME

Student Name: Denton R.
Location: Algebra II—Ms. B
Start time: 1:02

Date: 2/25/2015
Observer: Mr. D.
Stop time: 1:15

A: Antecedents	B: Behaviors	C: Consequences
1:03 Students get out books and open to begin class.	D. pulls out his cap and puts it on.	Students around D. start laughing and saying "Hey."
1:05 Teacher notices D. and tells him to remove his cap.	D. stands, slowly removes his cap, and bows.	Students applaud.
1:14 Teacher asks D. a question.	D. says, "Man, I don't know."	Another student says, "Yeah, you're stupid." Others laugh.

right difficulty level, providing assistance with these tasks, teaching the student how to request assistance, and teaching the student how to request a break from assigned work (Soodak & McCarthy, 2006; Umbreit, 1995).

At the classroom level, teachers are encouraged to use such preventive strategies as **precorrection**, which involves identifying the context for a student's misbehavior, clearly specifying the alternative expected behavior, modifying the situation to make the problem behavior less likely (e.g., providing a cue or moving the student away from tempting distractions), then rehearsing the expected positive behaviors in the new context and providing powerful reinforcers when the positive behaviors occur. Using PBS, teachers attempt to keep students engaged, provide a positive focus, consistently enforce school/class rules, correct disruptive behavior proactively, and plan for smooth transitions (J. Freiberg, 2006).

But PBS approaches are not only for the classroom or for students with special needs. At the whole school level, the teachers and administrators can:

- Agree on a common approach for supporting positive behaviors and correcting problems.
- Develop a few positively stated, specific behavioral expectations and procedures for teaching these expectations to all students.
- Identify a continuum of ways (from small and simple, to more complex and stronger) to acknowledge appropriate behaviors and correct behavioral errors.
- Integrate the positive behavior support procedures with the school's discipline policy.

Research shows that disciplinary referrals decrease when the whole school uses PBS approaches for all students, but the improvement are especially evident for students at the greatest risk for behavior problems (Bradshaw, Waasdorp, & Leaf, 2015). Because about 5% of students account for about 50% of the discipline referrals, it makes sense to develop interventions for those students. For example, a study comparing middle school students in a behavior support program with students outside the program showed that disciplinary referrals as well as verbal and physical aggression significantly decreased. In addition, students' perceptions of school safety improved (Metzler, Biglan, Rusby, & Sprague, 2001).

Even with newer approaches such as PBS, in recent years, most behavioral psychologists have found that operant conditioning offers too limited an explanation of learning. As behavioral approaches to learning developed, some researchers added a new element—self-management.

MyLab Education Video Example 7.4

The school shown here employs a schoolwide positive behavior support system.

Precorrection A tool for positive behavior support that involves identifying the context for a student's misbehavior, clearly specifying the alternative expected behavior, modifying the situation to make the problem behavior less likely, then rehearsing the expected positive behaviors in the new context and providing powerful reinforcers.

Self-Management

STOP & THINK What area of your life needs some self-management? Write down one behavior you would like to increase and one behavior you would like to eliminate. •

As you will see throughout this book, the role of students in managing their own learning is a major concern of psychologists and educators today. This concern is not restricted to any one group or theory. Different perspectives all converge on one important idea: that the responsibility and the ability to learn rest within the student. Students must be active—no one can learn for someone else (Butler, Schnellert, & Perry, 2017; Mace, Belfiore, & Hutchinson, 2001; B. H. Manning & Payne, 1996; Zimmerman & Schunk, 2004). From a behavioral perspective, students may be involved in any or all of the steps in a basic behavior change program. They may help set goals, observe their own work, keep records of it, and evaluate their own performance. Finally, they can select and deliver reinforcement.

GOAL SETTING. It appears that the goal-setting phase is very important in **self-management** (Reeve, 1996; Schunk, Meece, & Pintrich, 2014). Some research suggests that setting specific goals and making them public may be the critical elements of self-management programs. For example, years ago S. C. Hayes and his colleagues identified college students who had serious problems with studying and taught them how to set specific study goals. Students who set goals and announced them to the experimenters performed significantly better on tests covering the material they were studying than students who set goals privately and never revealed them to anyone (Hayes, Rosenfarb, Wulfert, Munt, Korn, & Zettle, 1985).

Higher standards tend to lead to higher performance (Locke & Latham, 2002). But what types of goals are important? If you read about the skills needed for 21st Century learning, you see goals such as *self-direction*, *problem solving*, *critical thinking*, *creativity*, *collaboration*, *communication*, and *social responsibility*. Perhaps you can work with your students to set specific goals that will help to develop these 21st Century skills (Butler, Schnellert, & Perry, 2017).

MONITORING AND EVALUATING PROGRESS. Students may also participate in the monitoring and evaluation phases of a behavior change program. These are the elements of self-management that most often are handled by the students themselves (Briesch & Chafouleas, 2009; Mace, Belfiore, & Hutchinson, 2001). Some examples of behaviors that are appropriate for self-monitoring are the number of assignments completed, time spent practicing a skill, number of books read, number of problems correct, and time taken to run a mile. Tasks that must be accomplished without teacher supervision, such as homework or private study, are also good candidates for self-monitoring. Students keep a chart, diary, or checklist that records the frequency or duration of the behaviors in question. A progress record card can help older students break down assignments into small steps, determine the best sequence for completing the steps, and keep track of daily progress by setting goals for each day. The record card itself serves as a cue that can be faded out.

Self-evaluation is somewhat more difficult than simple self-recording because it involves making a judgment about quality. Students can evaluate their behavior with reasonable accuracy, especially if they work with their teacher to co-construct criteria for judging a good performance or product (Butler, Schnellert, & Perry, 2017). One key to accurate self-evaluation seems to be for the teacher to periodically check students' assessments and give reinforcement for accurate judgments. Older students may learn accurate self-evaluation more readily than younger students. Self-correction can accompany self-evaluation. Students first evaluate, then alter and improve their work, and finally, compare the improvements to the standards again (Mace, Belfiore, & Hutchinson, 2001).

Self-management

Management of your own behavior and acceptance of responsibility for your own actions. Also the use of behavioral learning principles to change your own behavior.

GUIDELINES

FAMILY AND COMMUNITY PARTNERSHIPS

Applying Operant Conditioning: Student Self-Management

Introduce the system to parents and students in a positive way.*Examples*

1. Invite family participation and stress possible benefits to all family members.
2. Consider starting the program just with volunteers.
3. Describe how you use self-management programs yourself.

Help families and students establish reachable goals.*Examples*

1. Have examples of possible self-management goals for students such as starting homework early in the evening, or keeping track of books read.
2. Show families how to post goals and keep track of progress. Encourage everyone in the family to work on a goal.

Give families ways to record and evaluate their child's progress (or their own).*Examples*

1. Divide the work into easily measured steps.
2. Provide models of good work where judgments are more difficult, such as in creative writing.

3. Give families a record form or checklist to keep track of progress.

Encourage families to check the accuracy of student records from time to time, and help their children to develop forms of self-reinforcement.*Examples*

1. Have many checkups when students are first learning, and fewer later.
2. Have siblings check one another's records.
3. Where appropriate, test the skills that students are supposed to be developing at home and reward students whose self-evaluations match their test performances.
4. Have students brainstorm ideas with their families for rewarding themselves for jobs well done.

For more about self-management, see selfmanagementforkids.org

SELF-REINFORCEMENT. The last step in self-management is **self-reinforcement**. There is some disagreement, however, as to whether this step is actually necessary. Some psychologists believe that setting goals and monitoring progress alone are sufficient and that self-reinforcement adds nothing to the effects. Others believe that rewarding yourself for a job well done can lead to higher levels of performance than simply setting goals and keeping track of progress (Bandura, 1986). If you are willing to be tough and really deny yourself something you want until your goals are reached, then perhaps the promise of the reward can provide extra incentive for work. With that in mind, you may want to think of some way to reinforce yourself when you finish reading this chapter. A similar approach helped me write the chapter in the first place.

Sometimes, teaching students self-management can solve a problem for teachers and provide fringe benefits as well. For example, the coaches of a competitive swim team with members ages 9 to 16 were having difficulty persuading swimmers to maintain high work rates. Then the coaches drew up four charts indicating the training program to be followed by each member and posted the charts near the pool. The swimmers were given the responsibility of recording both their numbers of laps and their completion of each training unit. Because the recording was public, swimmers could see their own and their teammates' progress and keep accurate track of the work units completed. Work output increased by 27%. The coaches also liked the system because swimmers could begin to work immediately without waiting for instructions (McKenzie & Rushall, 1974).

At times, families can be enlisted to help their children develop self-management abilities. Working together, teachers and parents can focus on a few goals and, at the same time, support the growing independence of the students. The *Guidelines: Family and Community Partnerships* give some ideas.

Self-reinforcement

Controlling (selecting and administering) your own reinforcers.

CHALLENGES AND CRITICISMS

In this section we look at some of the challenges to earlier behavioral approaches to learning as well as some important criticisms and cautions.

Beyond Behaviorism: Bandura's Challenge and Observational Learning

Over 40 years ago, Albert Bandura (1977) noted that the traditional behavioral view of learning had many limitations. Sometimes Bandura has been characterized as a neo-behaviorist, but he has corrected that label:

At the time of my graduate training, the entire field of psychology was behaviorally oriented with an almost exclusive focus on the phenomenon of learning. But I never really fit the behavioral orthodoxy. At the time virtually all of the theorizing and research centered on learning through the effects of reinforcing outcomes. In my first major program of research, I argued against the primacy of conditioning in favor of observational learning, in which people neither emit responses nor receive reinforcements during the process of learning. (quoted in Pajares, 2008, p. 1)

In his early work, called **social learning theory**, Bandura pointed out two key distinctions between *enactive* and *observational* learning and between *learning* and *performance*.

ENACTIVE AND OBSERVATIONAL LEARNING. Bandura distinguished between enactive and vicarious, or observational, learning. **Enactive learning** is learning by doing and experiencing the consequences of your actions. This may sound like operant conditioning all over again, but it is not, and the difference has to do with the role of consequences. Proponents of operant conditioning believe that consequences strengthen or weaken behavior. In enactive learning, however, consequences are seen as providing information. Bandura emphasized reinforcement does not “stamp in” responses, but instead instills expectations about outcomes—what will happen if I do that behavior? In other words, our interpretations of the consequences create expectations, influence motivation, and shape beliefs (Schunk, 2016).

Vicarious learning is learning by observing others, so it often is called **observational learning**. For example, in one study of observational learning, college students learned as much from watching a video of a student being tutored about molecular diffusion as they did from being tutored themselves on the same subject (Muldner, Lam, & Chi, 2014). This challenges the behaviorist idea that cognitive factors are unnecessary in an explanation of learning. If people and even animals can learn by watching another person or animal learn, they must be focusing their attention, constructing images, remembering, analyzing, and making decisions that affect learning. Thus, much is going on mentally before behaviors can even take place. Cognitive apprenticeships, discussed in Chapter 10, are examples of vicarious learning—learning by observing others.

LEARNING AND PERFORMANCE. To explain some limitations of the behavioral model, Bandura also distinguished between the acquisition of knowledge (learning) and the observable performance based on that knowledge (behavior). In other words, Bandura suggested that we all may know more than we show. An example is found in one of Bandura's early studies (1965). Preschool children saw a film of a model kicking and punching an inflatable “Bobo” doll. One group saw the model rewarded for the aggression, another group saw the model punished, and a third group observed no consequences. When they were moved to a room with the Bobo doll, the children who had seen the punching and kicking reinforced on the film were the most aggressive toward the doll. Those who had seen the attacks punished were the least aggressive. But when the children were promised rewards for imitating the model's aggression, all of them demonstrated that they had learned the behavior.

Thus, incentives can affect performance. Even though learning may have occurred, it may not be demonstrated until the situation is appropriate or there are incentives to perform. This might explain why some students don't perform “bad behaviors” such as

Social learning theory

Theory that emphasizes learning through observation of others.

Enactive learning Learning by doing and experiencing the consequences of your actions.

Observational learning Learning by observation and imitation of others—vicarious learning.

POINT/COUNTERPOINT: Should Students Be Rewarded for Learning?

For years, educators and psychologists have debated whether students should be rewarded for schoolwork and academic accomplishments. For example, in the early 1990s, Paul Chance and Alfie Kohn exchanged opinions in several issues of *Phi Delta Kappan* (Chance, 1991, 1992, 1993; Kohn, 1993). I have included some quotes from Kohn and Chance because the debate was “lively” and thought provoking. A few years later, Judy Cameron and W. David Pierce (1996) published an article on reinforcement in the *Review of Educational Research* that precipitated extensive criticisms and rebuttals in the same journal from Mark Lepper, Mark Keavney, Michael Drake, Alfie Kohn, Richard Ryan, and Edward Deci (Kohn, 1996b; Lepper, Keavney, & Drake, 1996; R. M. Ryan & Deci, 1996). Many of the same people exchanged opinions in the November 1999 issue of *Psychological Bulletin* (Deci, Koestner, & Ryan, 1999; R. Eisenberg, Pierce, & Cameron, 1999). In 2014, the discussion continued in *Rewards: How to use rewards to help children learn and why teachers don’t use them well* (Walberg & Blast, 2014). What are the arguments?

POINT ▶ **Students are punished by rewards.** Years ago, Alfie Kohn (1993) argued that using rewards is a way to manipulate and control—“a way of doing things to children rather than working *with* them” (p. 784). He contended that rewards are ineffective because when the praise and prizes stop, the behaviors stop too. After analyzing 128 studies of extrinsic rewards, Edward Deci, Richard Koestner, and Richard Ryan (1999) concluded that “tangible rewards tend to have a substantial effect on intrinsic motivation, with the limiting conditions we have specified. Even when tangible rewards are offered as indicators of good performance, they typically decrease intrinsic motivation for interesting activities” (pp. 658–659). Kohn agreed:

All of this means that getting children to think about learning as a way to receive a sticker, a gold

star, or a grade—or even worse, to get money or a toy for a grade, which amounts to an extrinsic motivator for an extrinsic motivator—is likely to turn learning from an end into a means. Learning becomes something that must be gotten through in order to receive the reward. Take the depressingly pervasive program by which children receive certificates for pizzas when they have read a certain number of books. John Nicholls of the University of Illinois comments, only half in jest, that the likely consequence of this program is “a lot of fat kids who don’t like to read.” (1993, p. 785)

Another possible problem—Herbert Walberg and Joseph Blast (2014) suggest that Millennials (those born between the early 1980s to the 2000s) have been rewarded so much for just

swearing or smoking that they all see modeled by adults, peers, and the media. Personal consequences may discourage them from performing the behaviors. In other examples, children may have learned how to write the alphabet, but perform badly because their fine motor coordination is limited, or they may have learned how to simplify fractions, but perform badly on a test because they are anxious. In these cases, their performance is not an indication of their learning.

Bandura provided an alternative to the behavioral theories of the time. His work continued as he developed *social cognitive theory*—one of the most influential theories of learning and motivation in educational psychology today. We will devote Chapter 11 to a closer look at social cognitive theory.

Criticisms of Behavioral Methods

This chapter gave you an overview of several strategies for changing classroom behavior. However, you should be aware that these strategies are simply tools—they can be used either responsibly or irresponsibly. What, then, are some issues you should keep in mind?

PUT YOURSELF IN THEIR PLACE Imagine you are a graduate from my teacher education program being interviewed for your first job. The principal asks, “A teacher last year got in trouble for bribing his students with homework exemptions to get them to behave in class. What do you think about using rewards and punishments in teaching?” What will you say? •

participating, regardless of their actual performance, that they hold unrealistic expectations for recognition and promotions when they join the workforce.

► **Learning should be rewarding.** According to Paul Chance (1993):

COUNTERPOINT Skinner, unlike Kohn, understood that people learn best in a responsive environment. Teachers who praise or otherwise reward student performance provide such an environment. . . . If it is immoral to let students know they have answered questions correctly, to pat students on the back for a good effort, to show joy at a student's understanding of a concept, or to recognize the achievement of a goal by providing a gold star or a certificate—if this is immoral, then count me a sinner. (p. 788)

Do rewards undermine interest? R. Eisenberg and colleagues (1999) suggested “Reward procedures requiring specific high task performance convey a task's personal or social significance, increasing intrinsic motivation” (p. 677). Even psychologists such as Edward Deci and Mark Lepper who suggest that rewards might undermine intrinsic motivation agree that rewards can also be used positively. When rewards provide students with information about their growing mastery of a subject or when the rewards show appreciation for a job well done, then the rewards bolster confidence and make the task more interesting to the students, especially

students who lacked ability or interest in the task initially. Effective learning that leads to fast, automatic performance in math or reading requires extensive practice, especially in the early stages. Learning without rewards is more difficult—nothing succeeds like (recognized) success. The appropriate use of rewards helps students persist in the face of challenges (Walberg & Blast, 2014). And as Chance (1993) points out, if students master reading or mathematics with the support of rewards, they will not forget what they have learned when the praise stops. Would they have learned without the rewards? Some would, but some might not. Would you continue working for a company that didn't pay you, even though you liked the work? Will freelance writer Alfie Kohn, for that matter, lose interest in writing because he gets paid fees and royalties?

Beware of Either/Or. Cross-cultural research shows that rewards and evaluations can undermine creativity and interest in Western cultures, but they actually support creativity and interest in collectivist cultures such as China, South Korea, and Saudi Arabia. To quote Beth Hennessey, who summarized the results of these studies: “Rewards can be complicated. Culture is complicated. Teaching is complicated” (2015, p. 25). Ask any experienced teacher and you will find that rewards can have a place in the classroom. In fact, life in classrooms ought to be “rewarding” experiences. Many of those rewards come naturally with learning and being a member of the classroom community. But when some students need extra structure or incentives to get going, persist, practice, or resist distractions, then rewards could help support their efforts.

Source: From “Sticking Up for Rewards,” by P. Chance, June 1993, *Phi Delta Kappan*, pp. 787–790. Copyright © 1993 by Phi Delta Kappan. Reprinted with permission of Phi Delta Kappan and the author. From “Rewards versus Learning: A Response to Paul Chance,” by A. Kohn, June 1993, *Phi Delta Kappan*, pp. 783 and 785. Copyright © 1993 by Alfie Kohn. Reprinted from Phi Delta Kappan with the author's permission. From Hennessey, B. A. (2015). Reward, Task Motivation, Creativity and Teaching: Towards a Cross-Cultural Examination. *Teachers College Record*, 117, 10, pp. 1–28, <http://www.tcrecord.org> ID Number: 18099.

While you think about your answer to the *Stop & Think* question, look at the *Point/Counterpoint: Should Students Be Rewarded for Learning?* to see two different perspectives. Properly used, the strategies in this chapter can be effective tools to help students learn academically and grow in self-sufficiency. Effective tools, however, do not automatically produce excellent work, and behavioral strategies are often implemented haphazardly, inconsistently, incorrectly, or superficially (Landrum & Kauffman, 2006). The indiscriminate use of even the best tools can lead to difficulties.

Just as you must take into account the effects of a reward system on the individual, you must also consider its impact on other students. Is it possible that other students will learn to be “bad” in order to be included in the reward program? Most of the evidence on this question suggests that using individual adaptations such as reward programs does not have any adverse effects on students who are not participating if the teacher believes in the program and explains the reasons for using it to the nonparticipating students. If the conduct of some students does seem to deteriorate when their peers are involved in special programs, many of the same procedures discussed in this chapter should help them return to their previous levels of appropriate behavior (Chance, 1992, 1993).

Behavioral Approaches: Lessons for Teachers

There is great diversity in the learning histories of students. Each person in your class will come to you with different fears and anxieties. Some students may be terrified of speaking in public or of failing at competitive sports. Others will be anxious around various animals. Different activities or objects will serve as reinforcers for some students,

but not others. Some students will work for the promise of good grades—others could care less. All of your students will have learned different behaviors in their homes, neighborhoods, churches, or communities.

The research and theories presented in this chapter should help you understand how the learning histories of your students might have taught them to respond automatically to tests with sweaty palms and racing hearts—possible classical conditioning at work. Their learning histories might have included being reinforced for persistence, or for whining—operant conditioning at work. The chance to work in a group may be a reinforcer for some students and a punisher for others. Remember, what works for one student may not be right for another. And students can get “too much of a good thing”; reinforcers can lose their potency if they are overused.

Even though your students will have many different learning histories, there are some convergences—principles that apply to all people:

1. No one eagerly repeats behaviors that have been punished or ignored. Without some sense of progress, it is difficult to persist.
2. When actions lead to consequences that are positive for the person involved, those actions are likely to be repeated.
3. Teachers often fail to use reinforcement to recognize appropriate behavior; they respond instead to inappropriate behaviors, sometimes providing reinforcing attention in the process.
4. To be effective, praise must be a sincere recognition of a real accomplishment.
5. Whatever their current level of functioning, students can learn to be more self-managing.

MyLab Education Self-Check 7.5

▼ SUMMARY

Understanding Learning (pp. 290–292)

What is learning? Although theorists disagree about the definition of learning, most would agree that learning occurs when experience causes a change in a person’s knowledge or behavior. Changes simply caused by maturation, illness, fatigue, or hunger are excluded from a general definition of learning. Behavioral theorists emphasize the role of environmental stimuli in learning and focus on behavior—observable responses. Behavioral learning processes include contiguity learning, classical conditioning, operant conditioning, and observational learning.

Early Explanations of Learning: Contiguity and Classical Conditioning (pp. 292–294)

How does a neutral stimulus become a CS? In classical conditioning, which was discovered by Pavlov, a previously neutral stimulus is repeatedly paired with a stimulus that evokes an emotional or physiological response. Later, the previously neutral stimulus alone evokes the response—that is, the neutral stimulus is conditioned to bring forth a CR. The neutral stimulus has become a CS.

What are some everyday examples of classical conditioning? Here are a few—you can add your own: salivating when you smell your favorite foods, feeling tension when you hear a dentist’s drill, experiencing nervousness when you step on stage, becoming nervous when you step on an airplane.

Operant Conditioning: Trying New Responses (pp. 294–300)

What defines a consequence as a reinforcer? As a punisher? According to Skinner’s concept of operant conditioning, people learn through the effects of their deliberate responses.

For an individual, the effects of consequences following an action may serve as either reinforcers or punishers. A consequence is defined as a reinforcer if it strengthens or maintains the response that brought it about, but it is defined as a punishment if it decreases or suppresses the response that brought it about.

Negative reinforcement is often confused with punishment. How are they different? The process of reinforcement (positive or negative) always involves strengthening behavior. The teacher strengthens (reinforces) desired behaviors by removing something aversive as soon as the desired behaviors occur. Because the consequence involves removing or “subtracting” a stimulus, the reinforcement is negative. Punishment, on the other hand, involves decreasing or suppressing behavior. A behavior followed by a “punisher” is less likely to be repeated in similar situations in the future.

How can you encourage persistence in a behavior? Ratio schedules (based on the number of responses) encourage

higher rates of response, and variable schedules (based on varying numbers of responses or varying time intervals) encourage persistence of responses.

What a cueing? Cueing is the act of providing an antecedent stimulus just before a specific behavior is supposed to take place. Cueing is particularly useful in setting the stage for behaviors that must occur at a given time but are easily forgotten.

Putting It All Together: Applied Behavior Analysis (pp. 300–311)

What are the steps in applied behavior analysis? (1) Clearly specify the behavior to be changed and your goal. (2) Observe the current level of the behavior and possible causes. (2) Plan a specific intervention using antecedents, consequences, or both. (3) Keep track of the results, and modify the plan if necessary.

How can teachers use praise and reinforcers well? Teacher attention is a powerful reinforcer. Praise, if used appropriately, can support positive behaviors, but praise-and-ignore strategies all by themselves usually are not enough to change students' behaviors. The Premack principle states that a high-frequency behavior (a preferred activity) can be an effective reinforcer for a low-frequency behavior (a less-preferred activity). The best way to determine appropriate reinforcers for your students may be to watch what they do in their free time. For most students, talking, moving around the room, sitting near a friend, being exempt from assignments or tests, having computer time, or playing games are preferred activities.

When is shaping an appropriate approach? Shaping helps students develop new responses a little at a time, so it is useful for building complex skills, working toward difficult goals, and increasing persistence, endurance, accuracy, or speed. Because shaping is a time-consuming process, however, it should not be used if success can be attained through simpler methods such as cueing.

What are the managerial strategies for group consequences, contingency contracts, and token programs? Using group consequences involves basing reinforcement for the whole class on the behavior of the whole class. In a contingency contract program, the teacher draws up an individual contract with each student, describing exactly what the student must do to earn a particular privilege or reward. In token programs, students earn tokens (points, checks, holes punched in a card, chips, etc.) for both academic work and positive classroom behavior. Periodically, the students exchange the tokens they have earned for some desired reward. A teacher must use these programs with caution, emphasizing learning and not just "good" behavior.

What are some cautions in using punishment? Punishment in and of itself does not lead to any positive behavior or compassion for others, and it may interfere with developing caring relationships with students. Thus, whenever you consider the use of punishment, you should make it part of a two-pronged attack. First, carry out the punishment, and suppress the undesirable behavior. Second, make clear what the

student should be doing instead, and provide reinforcement for those desirable actions. Thus, while the problem behaviors are being suppressed, positive alternative responses are being strengthened.

Contemporary Applications: Functional Behavioral Assessment, Positive Behavior Supports, and Self-Management (pp. 311–316)

How can FBA and PBS be used to improve student behaviors?

In doing an FBA, a teacher studies the antecedents and consequences of problem behaviors to determine the reason or function of the behavior. Then, PBSs are designed to replace problem behaviors with new actions that serve the same purpose for the student, but do not have the same problems.

What are the steps in self-management? Students can apply behavior analysis on their own to manage their own behavior. Teachers can encourage the development of self-management skills by allowing students to participate in setting goals, keeping track of progress, evaluating accomplishments, and selecting and giving their own reinforcers.

Challenges and Criticisms (pp. 317–320)

What was Bandura's challenge to behavioral learning?

Bandura believed that the traditional behavioral view of learning had many limitations. Even though he was educated during a time when behavioral learning was dominant, his views never really fit the behavioral orthodoxy. He argued in favor of observational learning, in which people neither emit responses nor receive reinforcements during the process of learning.

Distinguish between enactive and vicarious (observational) learning. Enactive learning is learning by doing and experiencing the consequences of your actions. Vicarious (observational) learning is learning by observing, which challenges the behaviorist idea that cognitive factors are unnecessary in an explanation of learning. Much is going on mentally before performance and reinforcement can even take place. In behavioral views, reinforcement and punishment directly affect behavior. In social learning theory, seeing another person, a model, reinforced or punished can have similar effects on the observer's behavior. Social cognitive theory expanded social learning theory to include cognitive factors such as beliefs, expectations, and perceptions of self.

What is the difference between learning and performance?

Social learning theory recognized the differences between learning and performance—in other words, we all may know more than we show. You can learn something, but not perform it until the situation and incentives are right. Even though learning may have occurred, it may not be demonstrated until the situation is appropriate or there are incentives to perform.

What are the main criticisms of behavioral approaches? The misuse or abuse of behavioral learning methods is unethical. Critics of behavioral methods also point out the danger that reinforcement could decrease interest in learning by overemphasizing rewards and could have a negative impact on other students. Teachers must use behavioral learning principles appropriately and ethically.

MULTIPLE-CHOICE QUESTIONS

- Shyla taught at Happy Bee Preschool. To encourage her students to drink more water, she drew and handed each of them a smiley face on days when they had finished drinking a certain amount of water. On days when they failed to drink the required amount of water, she handed them frowny faces. Many of Shyla's colleagues found this to be an effective strategy, as preschoolers increased their water intake considerably. Which of the following would the smiley face in this case be an example of?
 - Reinforcer
 - Respondent
 - Operant
 - Stimulus control
- Rebecca, also from Happy Bee Preschool, wanted to try out a different method to encourage her students to increase their water intake. Which of the following methods would, in theory, lead to the best results on the following three counts: high response rate, slow declining rate, and persistent effect?
 - Reward students everyday when they accomplish their daily water intake goal.
 - Reward students only when they have accomplished their daily water intake goal for 10 consecutive days.
 - Reward only one out of five students everyday when they accomplish their daily water intake goal.
 - Reward every student weekly regardless of individual accomplishment.
- Ms. Jayakumar noticed that many of her preschool students did not seem to enjoy the reading class over their physical activity class. They did not pay attention during reading class and constantly looked outdoors longingly. As a result, Ms. Jayakumar decided to tell her students that they could play outdoors for an hour after they had finished reading the books assigned to them. What is this an example of?
 - Negative reinforcement
 - Successive approximations
 - Premack principle
 - Cueing

- Which of the following about handling undesirable behaviors is FALSE?
 - Soft, calm, and private reprimands are more effective than loud, public reprimands in discouraging undesirable behaviors.
 - The effectiveness of social isolation, or time out, is still under hot debate among scholars.
 - The goal of handling undesirable behaviors is to get students to promise behavioral change.
 - Overly harsh punishment might lead students to think about retaliation.

CONSTRUCTED-RESPONSE QUESTIONS

Case

Liang was one of the most frequently punished students in Mr. Ho's class owing partly to his late submissions of homework. In an effort to correct Liang's behavior, Mr. Ho imposed different forms of punishments on Liang, including public reprimand and additional homework. When Liang requested a meeting with Mr. Ho to discuss his situation, Mr. Ho refused and told Liang to reflect on his own. However, even after all these punishments, the situation did not improve, and, in fact, kept getting worse. Not only did Liang not submit any homework, he also actively avoided going to school on days when Mr. Ho's lesson was scheduled.

- The use of punishment in classroom can be tricky. Mr. Ho has acted unproductively in several ways. Identify what they are and explain why.
- Mr. Ho was using primarily punishment as a corrective method for Liang's behavior. However, some have argued that we should use positive reinforcement, whenever possible. How would you implement positive reinforcement strategies to improve Liang's behavior?

MyLab Education **Licensure Exam**

▼ WHAT WOULD THEY DO?

TEACHERS' CASEBOOK: Sick of Class

Here is how some expert teachers responded to the situation described at the beginning of the chapter about the disruptive student.

PAULA COLEMERE • Special Education Teacher

• English, History

McClintock High School, Tempe, AZ

If this is a chronic issue, I would conduct a functional behavior assessment (FBA) and develop a behavior intervention plan (BIP) to address the student's needs. The real problem here is the student's avoiding a task that he does not want to participate in. I would work with this student to find a way to make the task less daunting and try to ease his fears. If the student is just nervous about speaking in front of class, as many students are, maybe he can present in front of a smaller group. This way, the student is still working on the skill. I have had students who are terrified to read in class practice a small part of a passage with me to build confidence, and then I call on them in class to read in front of peers. If just escaping class is the function of the behavior, I would look to find a replacement for seeing the nurse. This would be tied to completing the task first. For example, "After you answer your question, you can deliver this to the office." This offers the student the movement as a reward for completing the task.

LINDA SPARKS • First-Grade Teacher

John F. Kennedy School, Billerica, MA

Every year, we always have a few "frequent flyers" to the nurse. Some just need to take a walk, while others try to remove themselves from an uncomfortable situation in the class where they think they may be made fun of, talked about, or put down. I always let them go in the beginning until the nurse or I have time to just observe and ask different questions. I find that when a child is away from the situation, he is more comfortable sharing what is going on. Sometimes it is as simple as he didn't complete an assignment, he is afraid he will make a mistake, or maybe something is happening at home. I had one student who tried to make himself sick daily. It was a new behavior, and we were trying to figure out what was going on. We called home and the parents assured us nothing had changed. We eventually found out that the parents were selling their home and the student overheard them talking on the phone about moving and looking at houses. After days of trying to put this together, he finally shared with me that he was afraid to be at school because he thought his mommy and daddy were going to move while he was at school and no one would be home when he got there. This is another instance where time is needed, trust needs to be earned, and compassion needs to be present.

JENNIFER L. MATZ • Sixth-Grade Teacher

Williams Valley Elementary, Tower City, PA

This type of behavior in students is usually attention seeking or avoidance of a situation. First, speak to the student privately. Tell him he seems to ask to see the nurse frequently. This causes him to miss valuable instruction time. Is there something about class that he doesn't like? When he opens up, explain that

many adults say their biggest fear in life is public speaking. This shows him he is not alone. Explain to him that unfortunately in life, there will be times you will have to do it. Share with him from your experience. Explain that some students have worked out a "signal" that they can use when they know the answer and are ready to speak. Work this out between the two of you so no one else would know. It could be something as simple as tugging on your earlobe or touching the tip of your nose. The signal should be something that is not obvious to anyone but you and the student. Make a deal with him that at first he must volunteer once a day. As he progresses, gradually increase how many times a day he should be volunteering.

JENNIFER PINCOSKI • Learning Resource Teacher: K-12

Lee County School District, Fort Myers, FL

The student's apparent anxiety over public speaking needs to be acknowledged. Punishing him or forcing him to participate will only worsen the situation. Steps can be taken to help the student become more comfortable with oral presentations, but in the meantime, alternate activities should be provided for him to demonstrate his knowledge.

Several things can be done to ease the student's anxiety. The teacher can meet with him beforehand to go over the assignment and let him practice without an audience. Students can then be divided into pairs so they only have to present to one other person; the first time, he can even be permitted to select his own partner (discussed privately, so he does not feel embarrassed). The pairs can gradually be increased to groups of 3, 4, and so on. Pairs and groups can be rotated so the student presents to all of his classmates, a few at a time. Students can also be paired up to work on the assignment and present it together.

The process of increasing this student's confidence with oral presentations will take time; patience and positive reinforcement are critical. Ultimately, it is most important to make sure he has adequate means of demonstrating his learning and being assessed on content objectives.

JESSICA N. MAHTABAN • Eighth-Grade Math

Woodrow Wilson Middle School, Clifton, NJ

I would first speak to the student alone and discuss my concerns. Together we would try to find a way for him to come up with various solutions to facing his fear. Maybe the student could start by just presenting to me and gradually we could add more people to the group until he is comfortable with the whole class. Or the student could tape record his presentation and play it to the class as part of the group presentation. If it were a severe case of a phobia, I would involve the school counselor, administration, school psychiatrist, the student, and, of course, his parents. Together we could address the child's needs. I don't feel rewards or punishment would help this situation. Students need to learn how to handle their problems on their own without always having a reward once the task is accomplished. Nor is it fair to feel the pressure of being punished if the task is not completed. The goal is to have all students be intrinsically motivated; in turn, this will help them to be prepared for the real world.

LAUREN ROLLINS • First-Grade Teacher

Boulevard Elementary School, Shaker Heights, OH

This student is clearly uncomfortable speaking in class. Punishing him for this would be a huge mistake! Instead, I would have an individual conference with him. During our meeting, I would tell him that I have noticed his frequent trips to the nurse when public speaking situations occur, and I would like to help him to overcome his fear. I would start by assuring him that his thoughts are important to me and offering him the opportunity to respond by writing his answers down, rather than sharing them aloud. I would also offer him the opportunity to give his oral presentations to me privately. Then, I would slowly raise my expectations for his class participation—asking him to contribute one response aloud each week, then twice, and so on. I would praise him and reward him for this in a way that would be motivating and meaningful to him. I would continue to add to my expectations until he felt comfortable being a participant in class discussions. As for oral presentations, as he became comfortable presenting to me one-on-one, I would ask him to invite one or two friends to his presentations and then a small group. My goal would be for him to slowly feel more and more comfortable presenting to a group of his choice. Eventually, my expectations for him would be the same as my expectations for the rest of his peers.

SARA VINCENT • Special Education Teacher

Langley High School, McLean, VA

The student is exhibiting task avoidance behavior. To extinguish the behavior of the student, modifications should first be made to the assignment. The student should have the choice to either perform the oral assignments in front of the teacher only or record his work in a location that is comfortable to him. Over time, the student can be introduced to a slightly larger group and given rewards when he completes the work. The rewards can slowly be faded until the student is comfortable with speaking in front of the class.

PAUL DRAGIN • ESL Teacher, Grades 9–12

Columbus East High School, Columbus OH

After speaking with the nurse and determining that there is no merit to the repeated trips, I would speak with the student and try to get him to open up about the possible fear that the classroom activity is provoking. Assuming that it is the fear of public speaking, I would propose some strategies to slowly integrate him into the oral activities by modifying the requirements and affirming his attempts. Fear of public speaking is common, and I would acknowledge this fact with all of the students and communicate why it is so important to practice this skill in the classroom setting.

chapter eight

COGNITIVE VIEWS OF LEARNING

TEACHERS' CASEBOOK: Remembering the Basics

You have just graded the first large unit test of the year. About two-thirds of the students seem to have mastered the material and understood the key ideas. The other third, however, seems to be totally lost. Somehow they failed to remember the basic vocabulary and facts—the foundation they must know before they can move on to the more complicated work in the next unit. These students often have trouble remembering key information from one day or week to the next.

CRITICAL THINKING

- How could you help these students retain and retrieve the necessary information?
- What are your options besides a rote memory approach?
- How would you use what the students already know to help them learn in better, more meaningful ways?
- How will these issues affect the grade levels you will teach?

WHAT WOULD YOU DO?

Gurgen Bakhshetyan/Shutterstock

OVERVIEW AND OBJECTIVES

We turn from behavioral theories of learning to the cognitive perspective in this chapter. This means a shift from “viewing the learners and their behaviors as products of incoming environmental stimuli” to seeing the learners as “sources of plans, intentions, goals, ideas, memories, and emotions actively used to attend to, select, and construct meaning from stimuli and knowledge from experience” (Wittrock, 1982, pp. 1–2). We will begin with a discussion of the general cognitive approach to learning and memory and the importance of knowledge in learning. To understand memory, we will consider early information processing models of memory, along with the recent improvements on those models suggested by findings in the interdisciplinary fields of cognitive science. These new models point to key processes of working memory, cognitive load, and knowledge. Then, we turn to ideas about how teachers can help their students become more knowledgeable. By the time you have completed this chapter, you should be able to:

- Objective 8.1 Differentiate between behavioral and cognitive views of learning, including the role of knowledge in the cognitive view.
- Objective 8.2 Explain early information processing models of memory and recent cognitive science models, including working memory, cognitive load theory, and individual differences in working memory.
- Objective 8.3 Describe current views of long-term memory, particularly the contents and types of long-term memory, individual differences, and the processes of retrieving information from long-term memory.
- Objective 8.4 Describe strategies for supporting students’ construction of long-lasting knowledge.

OUTLINE

Teachers' Casebook—Remembering the Basics: What Would You Do?

Overview and Objectives

Elements of the Cognitive Perspective

- The Brain and Cognitive Learning
- The Importance of Knowledge in Cognition

Cognitive Views of Memory

- Sensory Memory
- Working Memory
- Cognitive Load and Retaining Information
- Individual Differences in Working Memory
- Is Working Memory Really Separate?

Long-Term Memory

- Capacity and Duration of Long-Term Memory
- Contents of Long-Term Memory: Explicit (Declarative) Memories
- Contents of Long-Term memory: Implicit Memories
- Retrieving Information in Long-Term Memory
- Individual Differences in Long-Term Memory

Teaching for Deep, Long-Lasting Knowledge: Basic Principles and Applications

- Constructing Declarative Knowledge: Making Meaningful Connections
- Reaching Every Student: Make it Meaningful If You Have to Memorize ...
- Lessons for Teachers: Declarative Knowledge
- Development of Procedural Knowledge

Summary and Key Terms

Teachers' Casebook—Remembering the Basics: What Would They Do?

Cognitive view of learning

A general approach that views learning as an active mental process of acquiring, remembering, and using knowledge.

Cognitive science The interdisciplinary study of thinking, language, intelligence, knowledge creation, and the brain.

Mirror systems Areas of the brain that fire both during perception of an action by someone else and when performing the action.

ELEMENTS OF THE COGNITIVE PERSPECTIVE

The cognitive view is both the oldest and one of the youngest perspectives in psychology. It is old because discussions of the nature of knowledge, the value of reason, and the contents of the mind date back at least to the ancient Greek philosophers (Gluck, Mercado, & Myers, 2008). From the late 1800s until several decades ago, however, cognitive studies fell from favor and behaviorism thrived, with its emphasis on behavior change through external influences and laws of learning that apply to all higher organisms regardless of individual differences (Lee, 2016). But today, there is renewed interest in mental processes. The focus is the scientific study of memory and cognition—"understanding how the mind works, conducting empirical research into how people perceive, remember, and think" (Brown et al., 2014, p. 8). This **cognitive view of learning** can be described as a generally agreed-upon orientation that assumes humans are active information processors. Older cognitive views emphasized the *acquisition* of knowledge, but newer approaches stress its *construction* (Mayer, 2011; Ormrod, 2016). In the past few years, the study of memory and cognition has become interdisciplinary and often is called **cognitive science**—the study of thinking, language, and, increasingly, the brain (Radvansky & Ashcraft, 2014).

The Brain and Cognitive Learning

The human brain is made up of many different modules with specialized functions—recognizing faces, processing auditory information, extracting meaning from pictures, representing categories and concepts, forming new memories, coordinating movements, and many more. All these modules work together to make sense of your ongoing experiences and to learn. You start life with the gift of your genes, but through learning you shape your own intellectual capabilities. Throughout life, every time you learn, you change your brain (Anderson, 2015; Brown et al., 2014). For example, research has found that part of the brain hippocampus was

larger in taxi drivers than in other car drivers, and this increased size was related to the length of time the person had been driving a taxi. The explanation was that part of the brain grew larger because it was used more in navigating around the city. This same part of the brain is one of the first areas affected by Alzheimer's disease, which may help explain why people with Alzheimer's get lost even in familiar surroundings—their brain's navigation system is failing (Sleek, 2015).

Observing and visualizing support learning because the brain automatically responds to these types of stimulation. For example, when observing someone perform an action, the area of your brain that would be involved in the action is activated just by watching—the brain rehearses the action it sees another person perform. These areas of the brain that fire both during perception of an action and when actually performing the action have been called *mirror neurons* in monkeys (where they were first discovered) and **mirror systems** in humans, because the activated areas in humans contain millions of neurons (Anderson, 2015; Ehrenfeld, 2011). When you actually look at an object, a certain area of the brain is activated. Just mentally visualizing the object activates at least two-thirds of the same area of the brain (Ganis, Thompson, & Kosslyn, 2004).

The brain shapes and is shaped by cognitive processing activities. When we experience an event, different neurons in the brain fire together. Then, when we remember that event, the same neurons fire together again. With repeated activation, these neurons stabilize as a network through the hippocampus—a critical area of the brain for learning and forming new memories. Finally, the networks become memories stored in the neocortex, the thin outer layer of the brain. Of course, damage to any of these areas can affect learning. For example, years ago, when a patient's hippocampus was removed to treat severe epilepsy, the man could remember events and facts from his past, but could not form new memories, except for movements and physical skills like using a walker (Carey, 2015).

Because of the continuing development of the brain, particularly as the prefrontal cortex matures, children become more able to integrate past and present experiences by about age 7 or 8. An infant or a toddler reacts impulsively, but the 8-year-old can remember and reflect. Analysis, control, abstraction, memory space, speed of processing, and interconnection of information make self-regulation and continuing cognitive development possible. Many of these developmental and brain changes involve knowledge—a key element in the cognitive perspective.

The Importance of Knowledge in Cognition

STOP & THINK Quickly, list 10 terms that pertain to educational psychology. Now list 10 terms that relate to ceramic engineering. •

When you read *Stop & Think*, unless you are studying ceramic engineering, it probably took you longer to list 10 terms from that field than from educational psychology. Some of you may still be asking, “What is ceramic engineering anyway?” Your answers depend on your knowledge. (Think fiber optics, ceramic teeth and bones, ceramic semiconductors for computers, heat-shielding tiles for space shuttles.)

Knowledge and knowing are the outcomes of learning. When we learn the history of cognitive psychology, the products of ceramic engineering, or the rules of tennis, we know something new. However, knowing is more than the end product of previous learning; it also guides new learning. One of the most important elements in the learning process is what the individual brings to new learning situations. What we already know is the foundation and frame for constructing all future learning. Knowledge determines to a great extent what we will pay attention to, perceive, learn, remember, and forget (Bransford, Brown, & Cocking, 2000; Sawyer, 2006). Generally, what we know is helpful in learning because we build on current knowledge through *conceptual growth* and expansion. For example, compared to fourth-graders with little knowledge of soccer, fourth-graders who were soccer experts learned and remembered far more new soccer terms, even though the abilities of the two groups to learn and remember nonsoccer terms were the same. The difference was the soccer experts used their soccer knowledge to organize and cluster the soccer terms, which helped them remember (Schneider & Bjorklund, 1992). But at times, as we will see later, what we know is not helpful but misleading because we hold misconceptions about what we are trying to learn. In these situations, *conceptual change* rather than conceptual growth leads to understanding (APA, 2015; Lucariello et al., 2016).

GENERAL AND SPECIFIC KNOWLEDGE. Knowledge in the cognitive perspective includes both domain-specific and general knowledge. **Domain-specific knowledge** pertains to a particular task or subject. For example, knowing that the shortstop plays between second and third base is specific to the domain of baseball. Some knowledge, on the other hand, is general—it applies to many different situations. For example, **general knowledge** about how to read or focus your attention is useful both in and out of school.

Of course, there is no absolute line between general and domain-specific knowledge. When you were first learning to read, you may have studied specific facts about

MyLab Education
Podcast 8.1

In this podcast, textbook author Anita Woolfolk discusses not only the differences between behavioral, cognitive, and constructivist learning theories but also the importance of understanding and appreciating all three when thinking about learning.

MyLab Education
Video Example 8.1

The fourth-grade teacher in this video prompts students to connect prior knowledge with new learning. The cognitive approach suggests that one of the most important elements in the learning process is what the individual brings to new learning situations. What we already know is the foundation and frame for constructing all future learning.

Domain-specific knowledge
Information that is useful in a particular situation or that applies mainly to one specific topic.

General knowledge
Information that is useful in many different kinds of tasks; information that applies to many situations.

the sounds of letters. At that time, knowledge about letter sounds was specific to the domain of reading. But now you can use both knowledge about letter sounds and the ability to read in more general ways (Bruning, Schraw, & Norby, 2011; Schunk, 2016). And learning in school usually requires both domain-specific and general knowledge and skills. For example, Steven Hecht and Kevin Vagi (2010) followed students from fourth through fifth grade as the students were learning about fractions. Difficulty mastering fractions was associated both with lack of specific knowledge about fractions and lack of general knowledge about how to behave and pay attention in class.

Another way to categorize knowledge is as *declarative*, *procedural*, or *self-regulatory* (Schraw, 2006). You will encounter these terms throughout this chapter.

MyLab Education Video Example 8.2

The high-school students in this video are using domain-specific knowledge in their geometry lesson. Notice the use of declarative knowledge and procedural knowledge as students process new concepts.

DECLARATIVE, PROCEDURAL, AND SELF-REGULATORY KNOWLEDGE. **Declarative knowledge** is knowledge that can be declared, through words and symbol systems of all kinds—Braille, sign language, dance or musical notation, mathematical symbols, and so on. Declarative knowledge is “knowing that” something is the case. The range of declarative knowledge is tremendous. You can know very specific facts (the atomic weight of gold is 196.967), or generalities (leaves of some trees change color in autumn), or personal preferences (I don’t like lima beans), or rules (to divide fractions, invert the divisor and multiply). Small units of declarative knowledge can be organized into larger units; for example, principles of reinforcement and punishment can be organized in your thinking into a theory of behavioral learning.

Procedural knowledge is “knowing how” to do something such as divide fractions or design a Web site; it is knowledge in action. Procedural knowledge must be demonstrated. Notice that repeating the rule “to divide fractions, invert the divisor and multiply” shows declarative knowledge. The student can state the rule. But to show procedural knowledge, the student must act. When faced with a fraction to divide, the student must divide correctly. Students demonstrate procedural knowledge when they translate a passage into Spanish, correctly categorize a geometric shape, or craft a coherent paragraph.

Self-regulatory knowledge (sometimes called *conditional knowledge*) is knowing how to manage your learning—knowing how and when to use your declarative and procedural knowledge (Schraw, 2006). It takes self-regulatory knowledge to know when to read every word in a text and when to skim or when to apply a strategy for overcoming procrastination. For many students, this kind of knowledge is a stumbling block. They have the facts and can do the procedures, but they don’t seem to understand how to apply what they know at the appropriate time. Self-regulatory knowledge can be specific to a subject area (when to use the formula for calculating area, not perimeter, in geometry) or more general (how to summarize key points or use diagrams to organize information).

To have knowledge of something is to remember it over time and to be able to find it when you need it. Cognitive psychologists have studied memory extensively and have learned more about knowledge in the process. Let’s see what they have learned.

Declarative knowledge

Verbal information; facts; “knowing that” something is the case.

Procedural knowledge

Knowledge that is demonstrated when we perform a task; “knowing how.”

Self-regulatory knowledge

Knowing how to manage your learning, or knowing how and when to use your declarative and procedural knowledge.

Information processing

The human mind’s activity of taking in, storing, and using information.

MyLab Education Self-Check 8.1

COGNITIVE VIEWS OF MEMORY

There are a number of theories of memory, but the most common are the information processing explanations (Bruning et al., 2011; Radvansky & Ashcraft, 2014; Sternberg & Sternberg, 2012). We will use this well-researched framework for examining learning and memory.

Early **information processing** views of memory used the computer as a model. Like the computer, the human mind takes in information, performs operations on it to change its form and content, stores the information, retrieves it when needed, and generates responses to it (R. C. Atkinson & Shiffrin, 1968). According to this model, stimuli from the environment (input) flow into the *sensory registers*, one for each sensing modality

(seeing, hearing, tasting, etc.). From there, some information is encoded and moves to *short-term memory*. Short-term memory holds information very briefly, combines it with information from *long-term memory*, and with enough effort, moves some information into long-term memory storage.

This model proved helpful, but also incomplete. For example, in the model, information moved through the system mostly in one way, from sensory registers to short-term to long-term memory, but research indicated many more interactions and connections among the processes. The model could not explain how out-of-awareness memories or knowledge could influence learning or how several cognitive processes could happen simultaneously—like many small computers operating together.

Today, cognitive science views cognition as the operation of a very complex but coordinated system of multiple memory components interacting rapidly and simultaneously (Radvansky & Ashcraft, 2014). This newer perspective retains some of the features of the old approach, but emphasizes the role of working memory, attention, and the interactions among the elements of the system, as shown in Figure 8.1, which

FIGURE 8.1

A RECENT VERSION OF THE INFORMATION PROCESSING SYSTEM

Information is encoded in sensory memory, where perception and attention determine what will be held in working memory for further use. In working memory, executive processes manage the flow of information and integrate new information with knowledge from long-term memory. Thoroughly processed and connected information becomes part of long-term memory, and when activated again, becomes part of working memory. Implicit memories are formed without conscious effort. All three elements of the system interact with each other to guide perception; represent, organize, and interpret information; apply and modify propositions, concepts, images, schemas, and strategies; construct knowledge; and solve problems. Attention has a role in all three memory processes and in the interactions among them.

is based on several sources (Radvansky & Ashcraft, 2014; Schunk, 2016; Sternberg & Sternberg, 2012).

To understand this model, let's examine each element more carefully.

Sensory Memory

Stimuli from the environment (sights, sounds, smells, etc.) constantly bombard our body's mechanisms for seeing, hearing, tasting, smelling, and feeling. **Sensory memory** is the initial processing that transforms these incoming stimuli into perceptions that include meaning such as "oh, that sound is my doorbell" (Schunk, 2016).

Connect and Extend to PRAXIS II®

Attention (I, A1)

Attention has an important place in instructional activities. What steps can a teacher take to gain and maintain student attention during instruction?

CAPACITY, DURATION, AND CONTENTS OF SENSORY MEMORY. The capacity of sensory memory is very large, and it can take in more information than we can possibly handle at once—about 99% has to be discarded. But this vast amount of sensory information is fragile in duration. It lasts less than 3 seconds.

STOP & THINK Wave a pencil (or your finger) back and forth before your eyes while you stare straight ahead. What exactly do you see? Pinch your arm and let go. What do you feel just after you let go? •

You just experienced this brief holding of sensory information in your own sensory memory. You could see a trace of the pencil after the actual stimulus had been removed and feel the pinch after you let go. The sensory memory held information about the stimuli very briefly after the actual stimulus had ended (Lindsay & Norman, 1977).

The information content of sensory memory resembles the sensations from the original stimulus. Visual sensations are coded briefly as images, almost like photographs. Auditory sensations are coded as sound patterns, similar to echoes. It may be that the other senses also have their own codes. Thus, for a second or so, a wealth of data from sensory experience remains intact. In these moments, we have a chance to select and organize information for further processing. Perception and attention are critical at this stage.

PERCEPTION. The process of detecting a stimulus and assigning meaning to it is called **perception**. This meaning is constructed based on both physical representations from the world and our existing knowledge. For example, consider these marks: **B**.

If asked what the letter is, you would say "B." If asked what the number is, you would say "13." The actual marks remain the same; their meaning changes in keeping with your expectation to recognize a letter or a number and your knowledge of what Arabic numbers and the Latin alphabet look like. To a child without appropriate knowledge, the marks would probably be meaningless.

The process from sensory input to recognized objects probably goes through several stages. In the first phase, features are extracted, or analyzed, to give a rough sketch. This feature analysis has been called *data-driven* or **bottom-up processing** because the stimulus must be analyzed into features or components and assembled into a meaningful pattern "from the bottom up." For example, a capital letter A consists of two relatively straight lines joined at a 45-degree angle and a horizontal line through the middle. Whenever we see these features, or anything close enough, including  and  we are on the road to recognizing an A (J. R. Anderson, 2015). This explains how we are able to read words written in other people's handwriting, and why humans, but not computer bots, can fill in those annoying security codes such as .

As perception continues, the features may be organized into patterns. These processes were studied in Germany early in the twentieth century (and later in the United States) by psychologists called *Gestalt theorists*. **Gestalt**, which means "pattern" or "configuration" in German, refers to people's tendency to organize sensory information into patterns or relationships. Figure 8.2 presents a few Gestalt principles.

Sensory memory System that holds sensory information very briefly.

Perception Interpretation of sensory information.

Bottom-up processing Perceiving based on noticing separate defining features and assembling them into a recognizable pattern.

Gestalt German for *pattern* or *whole*. Gestalt theorists hold that people organize their perceptions into coherent wholes.

FIGURE 8.2

EXAMPLES OF GESTALT PRINCIPLES

Gestalt principles of perception explain how we “see” patterns in the world around us.

GESTALT PRINCIPLE	EXAMPLE	EXPLANATION
Figure-Ground		What do you see? Faces or a vase? Make one figure—the other ground.
Proximity		You see these lines as 3 groups because of the proximity of the lines.
Similarity		You see these lines as an alternating high/low pattern because of the similarity in height of lines.
Proximity Outweighing Similarity		Even though one line is short and one is taller, you see four groups of two lines each because the dissimilar two lines are closer together.
Common Direction		You see the elements of the pattern going in one direction.
Simplicity		You are likely to see the figures as two intersecting rectangles rather than five different odd shapes.
Closure		You perceive a circle instead of a series of curved lines.

If all perception relied only on feature analysis and Gestalt principles, learning would be very slow. Luckily, the features and patterns detected are combined in light of the context of the situation and our existing knowledge—called **top-down**, or conceptually driven, processing. So to recognize patterns rapidly, in addition to noting features, we use context and what we already know about the situation—our knowledge about words or pictures or the way the world generally operates. An example of context effects: in the series **A B C**, 13 is a *letter*, but in the series **12 B 14**, it is a *number* (Anderson, 2015; Eysenck, 2012). An example of knowledge effects: You have to know Latin letters and Arabic numbers to perceive a letter or a number. In Figure 8.1, the role of knowledge in perception is represented by the arrows between long-term memory (stored knowledge), working memory, and sensory memory.

THE ROLE OF ATTENTION. If every variation in color, movement, sound, smell, temperature, and other features ended up in working memory, life would be impossible. Early on, a part of the brain called the *reticular activating system* filters these masses of stimuli, mostly without any conscious effort on our part, so we are not bombarded (Schunk, 2016). Then, as processing proceeds, **attention** becomes more conscious and selective. What we pay attention to is guided to a certain extent by what we already know and what we need to know, so attention is involved in and influenced by all three memory processes shown in Figure 8.1. Attention is also affected by what else is happening at the time, by the type and complexity of the task, by the resources you bring to the situation, your expectations, and by your ability to control or focus your attention. Some students with attention-deficit disorder have great difficulty focusing attention or ignoring competing stimuli.

But attention takes effort and is a limited resource. I imagine you have to work a bit to pay attention to these words about attention! We can pay attention to only one cognitively demanding task at a time (Sternberg & Sternberg, 2012). For example, when I was learning to drive, I couldn't listen to the radio and drive at the same time. After some practice, I could listen, but I had to turn the radio off when traffic was heavy. After years of practice, I can plan a class, listen to the radio, and carry on a conversation as I drive. This is possible because many processes that initially require attention and concentration become automatic with practice.

Actually, **automaticity** probably is a matter of degree; we are not completely automatic, but rather more or less automatic in our performances depending on how much practice we have had, the situation, and whether we are intentionally focusing our attention and directing our own cognitive processing. For example, even experienced drivers might become very attentive and focused during a blinding blizzard—and no one should text or talk on a cell phone while driving. About 8 people die and 1,161 are injured *every day* as a result of texting, talking on a phone, or eating while driving, and hands-free equipment does not help (CDC, 2016). Nobody's driving is automatic enough to deal with these kinds of distraction.

Top-down Making sense of information by using context and what we already know about the situation; sometimes called *conceptually driven perception*.

Attention Focus on a stimulus.

Automaticity The ability to perform thoroughly learned tasks without much mental effort.

ATTENTION AND MULTITASKING. Speaking of distracted driving, drivers who text or chat on the phone say they are *multitasking*, and often they think all is fine (see the *Point/Counterpoint*). Adolescents are multitasking more than ever, perhaps because they have access to so much technology. For example, Moreno et al. (2012) provided actual real-time samples of the way many college students do homework (is this familiar?):

A student may pursue homework and have Facebook open in another window, send an email to a teaching assistant about a particularly challenging homework question, and intermittently browse the internet as a break from studying. Further, these clusters suggest that both at work and at play, college students' online activities typically involve multitasking. (p. 1101)

POINT/COUNTERPOINT: What's Wrong with Multitasking?

You may be multitasking right now. If so, close your Twitter, Instagram, Facebook, Vine, Reddit, YouTube, Snapchat, and email pages, and consider the arguments against and for multitasking.

POINT ▶ **Multitasking is bad for your brain.** In an article titled "Why the Modern World is Bad for Your Brain," Daniel Levitin (2015) cites fellow neuroscientist Earl Miller, one of the world's foremost experts on divided attention. Miller cautioned that our brains are "not wired to multitask well. . . . When people think they're multitasking, they're actually just switching from one task to another very rapidly. And every time they do, there's a cognitive cost in doing so" (Levitin, 2015, p. 2).

According to Levitin, even though we think we're getting a lot done, we are actually less efficient, more stressed, and basically overstimulated. Multitasking creates an addiction-like feedback loop. Novelty produced by switching tasks releases dopamine, which makes us want more novelty, leading to more multitasking. Toggling between tasks is rewarded with a burst of opioids—brain candy—there is no learning but it sure feels good. In addition, shifting attention burns the very kind of glucose fuel in your brain that you need to stay focused, so multitasking depletes this fuel quickly and causes you to feel exhausted, anxious, and even aggressive.

Other research shows that if you try to learn while multitasking, the new information goes to the wrong part of your brain, not to the hippocampus where it can be organized into more lasting memories (Foerde, Knowlton, & Poldrack, 2006). As soon as you turn your attention to something else, the brain starts to lose connections to what you were thinking about, like the answer to question 4 in your math assignment. To find that brain pathway again means repeating what you did to find the path in the first place, so finding the answer to question 4 takes more time. In fact, it can take up to 400% longer to do a homework assignment if you are multitasking (Paulos, 2007).

COUNTERPOINT ▶ **Multitasking can be effective—for a very few.** Multitasking is common and may work, at least for those people Jason Watson and David Strayer (2010) call "supertaskers." The researchers tested 200 undergraduates in a driving simulator; in addition to focusing on driving, they were multitasking by learning a list of words and simultaneously doing mental math. For the vast majority of drivers, performance—both driving and learning—suffered while they were multitasking. But for a small number (2.5%), performance did not suffer. A study of high school students found that about 15% of the participants performed better on simple tasks while they listened to music, had access to their phones, and were told to expect some emails. A word of warning however—these were very simple tasks like determining if a particular colored rectangle on a computer screen had moved. This was not calculus homework. Also, 85% of the high school students performed worse while multitasking, even on these simple assignments (Reddy, 2014).

Terry Judd (2013) summarizes the effects of multitasking for most people: "While there is some evidence that multitasking efficiency—that is, the mechanics of multitasking—can be improved through practice (Dux et al., 2009) any advantage this confers would appear to be more than offset by a reduction in the encoding of information acquired during multitasking into both shorter and longer-term memory" (p. 366). Still, is it possible that some adolescents who are growing up with multimedia are learning to be effective multitaskers?

Beware of Either/Or. Can we multitask effectively? Research at the Brain, Cognition, and Actions Laboratory at the University of Michigan says *it depends* (Hamilton, 2009). The content of the tasks makes a difference. Some tasks, such as walking and chewing gum, call on different cognitive and physical resources; and both walking and chewing are pretty automatic. But other complex tasks, such as driving and talking on the phone, require some of the same cognitive resources—paying attention to traffic and paying attention to what the caller is saying. The problem with multitasking comes with trying to do complex tasks simultaneously (Hamilton, 2009). So especially with driving, focus is critical. Remember, about 8 people die every day because of distracted driving. Even supertaskers shouldn't take a chance with their lives or the lives of other people.

Emails, texts, social networking sites, and ever-present phones all demand our attention. Multitasking seems like the only reasonable response to these demands, but is multitasking a good idea? As usual, it depends.

ATTENTION AND TEACHING. The first step in conscious learning is paying attention. Students cannot process information that they do not recognize or perceive (Lachter, Forster, & Ruthruff, 2004). But how successfully information is processed depends on several things, not just attention. Some tasks are *resource limited*. Performance on those tasks

GUIDELINES

Gaining and Maintaining Attention

Use signals.

Examples

1. Develop a signal that tells students to stop what they are doing and focus on you. Some teachers move to a particular spot in the room, flick the lights, tap the table, or play a chord on the class piano. Mix visual and auditory signals.
2. Avoid distracting behaviors, such as tapping a pencil while talking, that interfere with both signals and attention to learning.
3. Give short, clear directions before, not during, transitions.
4. Be playful with younger children: Use a dramatic voice, sensational hat, or clapping game (S. A. Miller, 2005).

Reach out rather than call out (S. A. Miller, 2005).

Examples

1. Walk to the child, look into his or her eyes.
2. Speak in a firm but nonthreatening voice.
3. Use the child's name.

Make sure the purpose of the lesson or assignment is clear to students.

Examples

1. Write the goals or objectives on the board, and discuss them with students before starting. Ask students to summarize or restate the goals.
2. Explain the reasons for learning, and ask students for examples of how they will apply their understanding of the material.

3. Tie the new material to previous lessons—show an outline or map of how the new topic fits with previous and upcoming material.

Incorporate variety, curiosity, and surprise.

Examples

1. Arouse curiosity with questions such as “What would happen if?”
2. Create shock by staging an unexpected event such as a loud argument just before a lesson on communication.
3. Alter the physical environment by changing the arrangement of the room or moving to a different setting.
4. Shift sensory channels by giving a lesson that requires students to touch, smell, or taste.
5. Use movements, gestures, and voice inflection—walk around the room, point, and speak softly and then more emphatically. (My husband has been known to jump up on his desk to make an important point in his college classes!)

Ask questions and provide frames for answering.

Examples

1. Ask students why the material is important, how they intend to study, and what strategies they will use.
2. Give students self-checking or self-editing guides that focus on common mistakes or have them work in pairs to improve each other's work—sometimes it is difficult to pay attention to your own errors.

For ideas about gaining student attention, see atozteacerstuff.com and search “get student attention.”

will improve if we allocate more resources, for example, turn off the phone and give the complicated lecture your full attention. Other tasks are *data limited*, which means that successful processing depends on the amount and quality of the data available. If the quality of the information available is inadequate, then no matter how hard we focus attention, we will not be successful. For example, if you just can't hear the lecture or if you know very few of the terms being used, more focused attention will not help you understand. We have already discussed a third kind of task—*automated*—that happens without much attention because we have practiced it so thoroughly, for example, the way an expert musician moves her fingers on the strings of a guitar (Bruning et al., 2011).

Many factors in the classroom influence student attention. Bright colors, underlining, highlighting of written or spoken words, calling students by name, surprise events, intriguing questions, variety in tasks and teaching methods, and changes in voice level, lighting, or pacing can all be used to *gain* attention. But then students have to *maintain* attention; they have to stay focused on the important features of the learning situation. The *Guidelines: Gaining and Maintaining Attention* offer ideas for capturing and maintaining students' attention.

Working Memory

Nelson Cowan defines **working memory** as “the small amount of information that can be held in mind and used in the execution of cognitive tasks, in contrast with long-term memory, which is the vast amount of information saved in one’s life” (2014, p. 197). Working memory is the “workbench” of the memory system, the interface where new information is held temporarily and combined with knowledge from long-term memory to perform cognitive tasks such as solving problems or comprehending a lecture. For example, when you see $45 \times 72 = ?$, you have to retrieve information such as what the $\times$ sign means and the arithmetic facts needed. So working memory holds what you are thinking about and using at the moment (Cowan, 2014; Demetriou, Spanoudis, & Mouyi, 2011).

A quick distinction—short-term memory is not the same as working memory. **Short-term memory** usually means just storage, the immediate memory for new information that fades very quickly. But working memory includes *both* temporary holding and active processing—the workbench idea again—where active mental effort is applied both to new input and to knowledge from your long-term memory.

CAPACITY OF WORKING MEMORY. Unlike sensory memory or long-term memory, working memory capacity is very limited—something many of your professors seem to forget as they race through a lecture while you labor to make sense of their words and PowerPoints. Early experiments suggested that the capacity of working memory was the “*magic 7*” *plus or minus 2* (so between 5 and 9) separate bits of new information (G. A. Miller, 1956). Later, we will see that this limitation can be overcome using strategies such as chunking or grouping, but the 5-to-9 item limit generally holds true in everyday life, at least for information without any particular meaning or context, such as strings of unrelated numbers. It is quite common to remember a new phone number after finding it on the Internet, as you make the call. But what if you have two phone calls to make in succession? Two new phone numbers (14 digits) probably cannot be held simultaneously.

Alan Baddeley and his colleagues are responsible for one common model of working memory that is central to our current understanding of human cognition (Baddeley, 2007; Eysenck, 2012; Fenesi, Sana, Kim, & Shore, 2015; Jarrold, Tam, Baddeley, & Harvey, 2011). In this model, working memory is composed of at least four elements: *the central executive* that controls attention and other mental resources (the “worker” of working memory), the *phonological loop* that holds verbal and acoustical (sound) information, the *visuospatial sketchpad* for visual and spatial information, and the *episodic buffer* where information from the phonological loop, visuospatial sketchpad, and long-term memory is integrated together to create meaningful representations based on all these sources.

The phonological loop and visuospatial sketchpad are short-term storage for sounds and images, so they are like what was considered short-term memory in earlier information processing models. The phonological loop, visuospatial sketchpad, and episodic buffer do some lower-level work for the central executive—holding on to and combining information. Baddeley also said there may be other lower-level worker/storage systems for different information such as smells or tastes, but the phonological loop, visuospatial sketchpad, and episodic buffer are the ones we know about. Figure 8.3 on the next page shows the working memory system.

Let’s experience the parts of the working memory system in action.

STOP & THINK Do some mental math to solve this problem from Ashcraft and Radvansky (2014, p. 152), and pay attention to how you go about the process:

$$\frac{(4 + 5) \times 2}{3 + (12/4)}$$

Connect and Extend to PRAXIS II®

Memory and Instruction (II, A1)

To maximize the learning derived from instructional activities, a teacher should be aware of the characteristics of working memory. Consider the techniques or tactics a teacher can employ that complement those characteristics.

Working memory The brain system that provides temporary holding and processing of information to accomplish complex cognitive tasks such as language comprehension, learning, and reasoning; the information that you are focusing on at a given moment.

Short-term memory Component of memory system that holds information for about 20 seconds.

FIGURE 8.3

THREE PARTS OF WORKING MEMORY

The central executive system is the pool of mental resources for such cognitive activities as focusing attention, reasoning, and comprehension. The phonological loop holds verbal and sound information, and the visuospatial sketchpad holds visual and spatial information. The episodic buffer integrates information from the phonological loop, visuospatial sketchpad, and long-term memory. The system is limited and can be overwhelmed if there is too much information or it is too difficult. The interaction among the components of working memory actually takes place in the long-term memory where the visuospatial sketchpad activates visual meaning (semantics) in long-term memory, the phonological loop activates verbal meaning (language), and long-term memory for events and episodes integrates all this visual and verbal information.

THE CENTRAL EXECUTIVE. As you solved the problem in *Stop & Think*, the central executive of your working memory focused your attention on the facts that you needed (what is $4 + 5$? what is $12/4$?), retrieved from your long-term memory the rules for which operations to do first, and recalled how to divide. The **central executive** supervises attention, makes plans, draws inferences, pushes out irrelevant thoughts, and decides what information to retrieve and how to allocate resources, as you can see in Figure 8.3.

THE PHONOLOGICAL LOOP. The **phonological loop** briefly holds verbal/sound information and keeps it active by keeping it “in the loop”—rehearsing and paying attention to the information. The short-term storage of the phonological loop is where you put the “18” ($4 + 5 = 9$; $9 \times 2 = 18$) from the top line of the problem while you calculated the $3 + (12/4)$ on the bottom of the problem. Baddeley (2001, 2007) suggests that we can hold as much in the phonological loop as we can rehearse (say to ourselves) in 1.5 to 2 seconds. The 7-digit telephone number fits this limitation. But what if you tried to hold these 7 words in mind: *disentangle appropriation gossamer anti-intellectual preventative foreclosure documentation* (Gray, 2011)? Besides being a mouthful, these words take longer than 2 seconds to rehearse so they are more difficult to hold in working memory than 7 single digits or 7 short words. In addition, some of the words may be unfamiliar to you, which makes them harder to rehearse.

Remember—put in your working memory—that we are discussing temporarily holding new information. In daily life we certainly can hold more than 5 to 9 bits or 1.5 seconds of information at once. While you are keying in that 7-digit phone number you just looked up, you are bound to have other things “on your mind”—in

Central executive The part of working memory that is responsible for monitoring and directing attention and other mental resources.

Phonological loop Part of working memory. A speech- and sound-related system for holding and rehearsing (refreshing) words and sounds in short-term memory for about 1.5 to 2 seconds.

your memory—such as how to use a phone, whom you are calling, and why. You don't have to pay attention to these things; they are not new knowledge. Some of the processes, such as using the touchpad on the phone, are *automated* tasks. However, because of the working memory's limitations, if you were in a foreign country and were attempting to use an unfamiliar public telephone system, you might very well have trouble remembering the phone number because your central executive was searching for strategies to use the phone system at the same time. Even a few bits of new information can be too much to hold in working memory if the new information is very complex, meaningless, or unfamiliar or if you have to integrate several elements to make sense of a situation (Sweller, van Merriënboer, & Paas, 1998).

THE VISUOSPATIAL SKETCHPAD. Now try the problem shown in the next *Stop & Think*.

STOP & THINK If you rotate a *d* 180 degrees clockwise, do you get a *b* or a *p*? •

Most people answer this question by creating a visual image of a *d* and rotating it. The **visuospatial sketchpad** is the place in your mind where you manipulated the image (after your central executive retrieved the meaning of “180 degrees,” and “clockwise,” of course). You can use your phonological loop and your visuospatial sketchpad at the same time, but each is quickly filled and easily overburdened. Each kind of task—verbal and visual—appears to happen in different areas of the brain, and there are some individual differences in the capacities of these systems, too (Gray, 2011; Radvansky & Ashcraft, 2014).

THE EPISODIC BUFFER. If working memory is the workbench of memory, the episodic buffer is the workbench of working memory. The **episodic buffer** is the process that brings together and integrates information from the phonological loop, visuospatial sketchpad, and long-term memory under the supervision of the central executive, to create complex memories, such as storing the appearance, voice, words, and actions of an actor in a film to create a complete character.

THE DURATION AND CONTENTS OF WORKING MEMORY. It is clear that the duration of information in the working memory system is short, about 5 to maybe 20 seconds, unless you keep rehearsing the information or process it in some other way (Baddeley, 2001). It may seem to you that a memory system with a 20-second time limit is not very useful, but without this system, you would have already forgotten what you read in the first part of this sentence before you came to these last few words. This would clearly make understanding sentences difficult.

The contents of information in working memory may be in the form of sounds and images that resemble the representations in sensory memory, or the information may be structured more abstractly, based on meaning.

Cognitive Load and Retaining Information

Cognitive load is a term that refers to the amount of mental resources, mostly working memory, required to perform a particular task. The concept is really important for teachers because the central idea of cognitive load theory is that “human cognitive architecture—especially the limitations of working memory—should be taken into account when designing instruction” (Leppink, Paas, van Gog, van der Vleuten, & van Merriënboer, 2014, p. 32). This brings us back to that professor who raced through a lecture, taxing your working memory. Guess the professor didn't understand cognitive load theory. Some tasks make more demands than others on working memory.

MyLab Education
Video Example 8.3

The adolescent in this video describes methods she uses to remember what she learns at school. Note her strategies for holding information in her working memory.

Visuospatial sketchpad

Part of working memory. A holding system for visual and spatial information.

Episodic buffer The process that brings together and integrates information from the phonological loop, visuospatial sketchpad, and long-term memory under the supervision of the central executive.

Cognitive load The volume of resources necessary to complete a task.

TWO KINDS OF COGNITIVE LOAD. The cognitive load of a task is not an absolute “weight.” The actual cognitive load in a given situation depends on many things, including what the person already knows about the task and what instructional supports are available (Kalyuga, Rikers, & Paas, 2012). There are different kinds cognitive load, but two are especially critical for teaching. One is unavoidable for learning and the other gets in the way.

Intrinsic cognitive load is unavoidable—it is the amount of cognitive processing required to figure out the material. That amount depends on how many elements you have to take into account at one time (charts, graphs, text, lecture, PowerPoints, pictures, Web information . . .), how complicated the interactions among the elements are, and your level of expertise in the subject (Leppink et al., 2014). Even though working memory can hold 5 to 9 new bits of information, it can *work with* only about 2 to 4 at a time, so if you have to understand how many separate elements interact in a complex system, such as grasping the structure and function of DNA by reading text and looking at graphs, you will be in trouble unless you already understand some of the parts: vocabulary, concepts, procedures, and so on (van Merriënboer & Sweller, 2005). Intrinsic cognitive load is essential to the task—it cannot be eliminated. But good instruction can help manage intrinsic load.

Extraneous cognitive load is the cognitive capacity you use to deal with problems not related to the learning task, like trying to get your roommate (spouse, children, partner) to quit interrupting you or struggling with a disorganized lecture or a poorly written textbook (not this one of course!). Some educational psychologists also talk about a third factor, *germane cognitive load* or *germane resources*, meaning how you allocate your working memory resources as you are trying to learn (Choi, van Merriënboer, & Paas, 2015; Tricot & Sweller, 2014).

The goal of good instructional design and good teaching is to *manage* intrinsic load (keep it just right for the students’ abilities—in their zone of proximal development) and *reduce* extraneous load (clear away as much as possible). For example, teachers can provide worked examples and other supports, focus attention on the main ideas, and generally supply scaffolding (see Chapter 2). You also might have students explain the material to each other or to themselves, draw or chart their understandings, take useful notes, and apply other strategies we will discuss in upcoming chapters (Berthold & Renkl, 2009; Mayer, 2011; van Gog et al., 2010). The two kinds of cognitive load are summarized in Table 8.1.

RETAINING INFORMATION IN WORKING MEMORY. Information in working memory must be kept activated in order for it to be retrieved easily. Activation is high as long as you are focusing on information, but activation decays or fades quickly when attention shifts away. Holding information in working memory is like a circus performer keeping a series of plates spinning on top of several poles. The performer gets one plate spinning, moves to the next plate, and the next, but has to return to the first plate before it slows down too much and falls off its pole. If we don’t keep the information “spinning” in working memory—keep it activated—it will “fall off” (Anderson, 1995, 2015). When activation fades, forgetting follows.

To keep information activated, most people continue rehearsing the information mentally. There are two types of rehearsal. **Maintenance rehearsal** involves repeating the information in your phonological loop or refreshing information in your visuospatial sketchpad. As long as you revisit (repeat, reimage) the information, it can be maintained in working memory indefinitely. Maintenance rehearsal is useful for retaining something you plan to use and then forget, such as a phone number or a location on a map.

Elaborative rehearsal involves connecting the information you are trying to remember with something you already know—with knowledge from long-term memory. For example, if you meet someone at a party whose name is the same as your brother’s, you don’t have to repeat the name to keep it in memory; you just have to make the

Intrinsic cognitive load

The resources required by the task itself, regardless of other stimuli.

Extraneous cognitive load

The resources required to process stimuli irrelevant to the task.

Maintenance rehearsal

Keeping information in working memory by repeating it to yourself.

Elaborative rehearsal

Keeping information in working memory by associating it with something else you already know.

TABLE 8.1 • Two Kinds of Cognitive Load

There are two types of cognitive load that make demands during learning, with different causes and effects.

TYPE OF COGNITIVE LOAD	WHAT IS IT?	WHAT CAUSES IT?	WHAT'S AN EXAMPLE?	MANAGING
Intrinsic	<i>Unavoidable</i> : the essential processing needed to attend to and make sense of the material	Caused by the inherent complexity of the task (how many elements and interactions): the more complex, the more basic processing needed	More intrinsic processing needed to recognize and organize a complicated task such as quadratic equations for novices	Be sure task fits students' abilities and current knowledge; focus attention on main ideas; review often; give multiple examples including worked out examples
Extraneous	<i>Avoidable or manageable</i> : unhelpful processing needed to deal with problems that are not related to the learning task itself	Caused by poor learning strategies, divided attention and distractibility, poor instruction, inadequate background knowledge	Students scan back and forth between the text and a graph, but don't know how to read the graph or integrate the visual and verbal information	Remove distractions; teach key vocabulary/concepts needed; have students explain to each other; teach and practice appropriate learning strategies

Source: Based on Bruning, R. H., Schraw, G. J., & Norby, M. M. (2011). *Cognitive Psychology and Instruction* (5th ed.). Boston, MA: Pearson, Mayer, R. E. (2011). *Applying the Science of Learning*. Boston, MA: Pearson.

connection. This kind of rehearsal not only retains information in working memory but also helps create long-term memories. Rehearsal is a process the central executive controls to manage the flow of information in the information processing system (Radvansky & Ashcraft, 2014).

LEVELS OF PROCESSING THEORY. Craik and Lockhart (1972) first proposed their **levels of processing theory** (sometimes called *depth of processing theory*) as an alternative to short-/long-term memory models, but levels of processing theory is particularly related to the notion of elaborative rehearsal. Craik and Lockhart suggested that the length of time that information is remembered is determined by the extent to which the information is analyzed and connected with other information. The more completely and deeply information is processed, the better are our chances of remembering it. For example, according to the levels of processing theory, if I ask you to sort pictures of dogs based on the color of their coats, you might not remember many of the pictures later. But if I ask you to rate each dog on how likely it is to chase you as you jog, you probably would remember more of the pictures. To rate the dogs, you must pay attention to details in the pictures, relate features of the dogs to characteristics associated with danger, remember your experiences with dogs, and so on. This rating procedure requires elaborative rehearsal (associating the information with what you already know), so processing is deeper and more focused on the *meaning*, not the surface features, of the photos. Levels of processing theory has had problems, but it does make sense that we will learn and remember more when we apply some effort than when we just skim the surface (Brown et al., 2014).

The limited capacity of working memory can also be somewhat circumvented by the process of **chunking**. Because the number of bits of information, not the size of each bit, is a limitation for working memory, you can retain more information if you can

Levels of processing theory Theory that recall of information is based on how deeply it is processed.

Chunking Grouping individual bits of data into meaningful larger units.

group individual bits of information. You can experience this effect of chunking by trying to hold these letters in memory:

HBOUSACIALOLATM

Now try these:

HBO USA CIA LOL ATM

You just used chunking to group the string of letters into memorable (and meaningful) chunks, so you could hold more in memory. Also, you brought your knowledge of the world to bear on the memory task. Chunking helps you remember a password or social security number.

FORGETTING. Information may be lost from working memory through *interference* or *decay*. **Interference** is fairly straightforward: Processing new information interferes or gets confused with old information. As new thoughts accumulate, old information is lost from working memory. Information is also lost by time **decay**. If you don't continue to pay attention to information, the activation level decays (weakens) and finally drops so low that the information cannot be reactivated—it disappears altogether. Some new research, however, suggests there is a kind of memory that seems forgotten but is really just “on hold”—neural traces of recent memories that are “asleep” but might be awakened with the right stimulation (Pinker, 2017; Rose et al., 2016).

Actually, forgetting is very useful. Without forgetting, people would quickly overload their working memories and learning would cease. Also, it would be a problem if you remembered permanently every sentence you ever read, every sound you ever heard, every picture you ever saw . . . you get the idea. Finding a particular bit of information in all that sea of knowledge would be impossible. It is helpful to have a system that provides temporary storage and that “weeds out” some information from everything you experience.

Individual Differences in Working Memory

Working memory capacity is a good predictor of a range of cognitive skills including language understanding, reading and mathematics abilities, and fluid intelligence. As you might expect, there are both developmental and individual differences in working memory.

DEVELOPMENTAL DIFFERENCES. All of the components of working memory are in place by about age 4. Performance on working memory tasks improves steadily over the elementary and secondary school years, but visual/spatial memory appears to develop earlier. Three basic aspects of memory improve over time: memory span or the amount of information that can be held in working memory, memory processing efficiency, and speed of processing. These three basic capacities act together and influence each other; more efficient processing allows greater amounts to be held in memory, for example (Demetriou, Christou, Spanoudis, & Platsidou, 2002). You experienced this effect of efficient processing when you remembered HBOUSACIALOLATM by chunking the letters into HBO USA CIA LOL ATM. Your more efficient and faster processing expanded your memory span.

Young children have fewer strategies and less knowledge, so they have more trouble with memorizing. But as they grow older, children develop more effective strategies for remembering information. Most children spontaneously discover rehearsal around age 5 or 6 and continue to use this strategy. Also around age 6, most children discover the value of using organizational strategies, and by 9 or 10, they use these strategies spontaneously. So, given the following words to learn:

couch, orange, rat, lamp, pear, sheep, banana, rug, pineapple, horse, table, dog

an older child or an adult might organize the words into three short lists of *furniture*, *fruit*, and *animals*. Also remember that expertise in an area helps you use categories to

Interference The process that occurs when remembering certain information is hampered by the presence of other information.

Decay The weakening and fading of memories with the passage of time.

organize and remember, as we saw with the expert fourth-grade soccer players earlier. Younger children can be taught to use rehearsal or organization to improve memory, but they probably won't apply the strategies unless they are reminded. Children also become more able to use elaboration as they mature, but this strategy develops late in childhood. Creating images or stories to assist in remembering ideas is more likely for older elementary school students and adolescents (Siegler, 1998).

So, through changes in the brain, faster processing of information, the development and automating of strategies, and added knowledge, working memory increases in capacity from ages 4 through adolescence (T. P. Alloway et al., 2006; Gathercole, Pickering, Ambridge, & Wearing, 2004). Children are 10 to 11 years old before they have adult-like memories (Bauer, 2006).

INDIVIDUAL DIFFERENCES. Besides developmental differences, there are other individual variations in working memory, and these differences have implications for learning. Try the *Stop & Think* exercise.

STOP & THINK Read the following sentences and words in caps out loud once:

For many years my family and friends have been working on the farm. SPOT
Because the room was stuffy, Bob went outside for some fresh air. TRAIL
We were fifty miles out to sea before we lost sight of the land. BAND

Now cover the sentences and answer these questions (be honest):

Name the words that were in all caps. Who was in the stuffy room? Who worked on the farm? •

You have just taken a few items from a test of working memory span (Engle, 2001). The test required you to both process and store—process the meaning of the sentences and store the words. How did you do?

The more educational psychologists study working memory, the more we realize how important it is in learning and development at every age (T. P. Alloway, Banner, & Smith, 2010; Welsh, Nix, Blair, Bierman, & Nelson, 2010). For adolescents and adults, the correlation between scores on a test of working memory span (like the one you just took in the *Stop & Think* exercise) and the verbal portion of the Scholastic Assessment Test (SAT) is about .59. But there is no correlation between the SAT and simple short-term memory span (repeating digits). For elementary school students, growth in working memory (but not simple short-term memory) is related to reading abilities and reading comprehension; problems with working memory are associated with reading disabilities. Working memory is related to academic achievement in math, reading, written language, and second language learning, with correlations from .3 to .9 depending on the study (Fenesi et al., 2015; Peng, Namkung, Barnes, & Sun, 2016). For young children, growth in working memory and attention control during the preschool years predicts emergent literacy and number skills. But beware: Working memory performance can vary across the school day and week, so your students can have good days and bad days for learning (Dirk & Schmiedek, 2016).

Working memory span is also related to scores on intelligence tests (Swanson, 2014). Some people seem to have more efficient working memories than others (Cariglia-Bull & Pressley, 1990; DiVesta & Di Cintio, 1997; Jurden, 1995), and differences in working memory may be associated with giftedness in math and verbal areas.

Is Working Memory Really Separate?

Recently, some psychologists have suggested that working and long-term memory are not two separate memory stores. Rather, working memory is the part of long-term memory that works on (processes) currently activated information. The difference between

working memory and long-term memory may be whether a particular memory is currently being used or is “activated.” Working memory is the current “focus of attention” in long-term memory (Cowan, 2008, 2014; Fenesi et al., 2015; Schweppe & Rummer, 2014). Whether working memory is separate from or a part of long-term memory, it is clear that forming and finding long-term memories is a key to learning. Because this is such an important topic for teachers, we will spend quite a bit of time on it.

MyLab Education **Self-Check 8.2**

LONG-TERM MEMORY

Working memory holds the information that is currently activated, such as the name of the person you just met. **Long-term memory** holds the information that is well learned, such as the names of all the people you know.

Capacity and Duration of Long-Term Memory

There are a number of differences between working and long-term memory. Information enters working memory very quickly, but it takes time and effort to store memories for the long term. The *capacity* of working memory is limited, but the capacity of long-term memory appears to be, for all practical purposes, unlimited. And once information is securely stored in long-term memory, its *duration* there can be permanent—it can be stored forever under the right conditions. Our access to information in working memory is immediate because we are thinking about the information at that very moment. But gaining access to information in long-term memory can require time and effort.

Most cognitive psychologists believe there are two kinds of long-term memory—explicit and implicit—with subdivisions under each category, as shown in Figure 8.4. **Explicit memory** is knowledge from long-term memory that can be recalled, consciously considered, and declared (so this is basically declarative knowledge, as we defined earlier in the chapter—you remember that, right?). We are aware of these memories; we know we have remembered them. **Implicit memory**, on the other hand, is knowledge that

FIGURE 8.4

LONG-TERM MEMORY: EXPLICIT AND IMPLICIT

Explicit and implicit memory systems follow different rules and involve different neural systems of the brain. The subdivisions of each kind of memory also may involve different neural systems.

Long-term memory

Permanent store of knowledge.

Explicit memory Long-term memories that involve deliberate or conscious recall.

Implicit memory

Knowledge that we are not conscious of recalling but that influences our behavior or thought without our awareness.

Source: From *Psychology* by Peter Gray. Published by Worth Publishers. Copyright © 1991, 1994, 1999, 2002, 2011 by Worth Publishers. Adapted with permission from Worth Publishers.

we are not conscious of recalling, but that influences behavior or thought without our awareness. These different kinds of memory are associated with different parts of the brain (Radvansky & Ashcraft, 2014; Gray, 2011). These two kinds of memories are the *contents* of long-term memory.

Contents of Long-Term Memory: Explicit (Declarative) Memories

Explicit memories are what we usually consider to be knowledge—the things that we know we know and can declare—so this type of memory is sometimes called *declarative memory*. In Figure 8.4, you can see that explicit (declarative) memories can be either semantic (based on meaning) or episodic (based on the sequence of events, such as memory for your own experiences).

Semantic memory, very important in schools, is memory for meaning, including words, facts, theories, and concepts. These memories are not tied to particular experiences and are represented and stored as *propositions*, *images*, *concepts*, and *schemas* (J. R. Anderson, 2015; Schraw, 2006).

PROPOSITIONS AND PROPOSITIONAL NETWORKS. How do we represent the meaning of sentences and pictures in our memories? One answer is with propositions connected in networks. A proposition is the smallest unit of knowledge that can be judged true or false. John Anderson (2015, pp. 104–105) gives this example of a statement with three propositions: “Lincoln, who was president of the United States during a bitter war, freed the slaves.” The three basic propositions are:

1. Lincoln was president of the United States during a war.
2. The war was bitter.
3. Lincoln freed the slaves.

Propositions that share information are linked in what cognitive psychologists call **propositional networks**. It is the meaning, not the exact words or word order, that is stored in the network. The same propositional network would apply to the sentence: “The slaves were freed by Lincoln, who, during a bitter war, was president of the United States.” The meaning is the same, and it is this meaning that is stored in memory as a set of relationships among propositions.

It is possible that most information is stored and represented in propositional networks. When we want to recall a bit of information, we can translate its meaning (as represented in the propositional network) into familiar phrases and sentences, or mental pictures. Also, because propositions are networked, the recall of one bit of information can trigger or activate recall of another. We are not aware of these networks because they are not part of our conscious memory (J. R. Anderson, 2015). In much the same way, we are not aware of underlying grammatical structure when we form a sentence in our own language; we don’t have to label parts of speech to be able to speak.

IMAGES. **Images** are representations based on the structure or appearance of the information (J. R. Anderson, 2015). As we form images (like you did in the rotating *d* problem), we try to remember or recreate the physical attributes and spatial structure of information. For example, when asked what store is beside the Starbucks at a particular intersection in town, many people would use “their mind’s eye” to view the intersection and then “look” beside the Starbucks. However, researchers don’t agree on exactly how images are stored in memory. Some psychologists believe that images are stored as pictures; others believe we store propositions in long-term memory (“Target is beside Starbucks”) and convert to pictures in working memory when necessary. The debate continues (Sternberg & Sternberg, 2012).

Features of each process probably are involved—some memory for images and some verbal descriptions of the image. Seeing images “in your mind’s eye” is not exactly the same as seeing the actual image. It is more difficult to perform complicated transformations on mental images than it is on real images. For example, if you had a plastic *d* magnet on your refrigerator, you could very quickly rotate it. Rotating mentally takes more time for most people. And it is easier to form images for some words or concepts

Semantic memory
Memory for meaning.

Propositional network Set of interconnected concepts and relationships in which long-term knowledge is held.

Images Representations based on the physical attributes—the appearance—of information.

than others. It is probably easier for you to form an image of *Starbucks* than one of *justice*, for example. Nevertheless, images are useful in making many practical decisions such as how a sofa might look in your living room or how to line up a golf shot. Images may also be helpful in abstract reasoning. Physicists such as Faraday, Feynman, and Einstein reported creating images to reason about complex new problems. Einstein claimed that he was visualizing chasing a beam of light and catching up to it when the concept of relativity came to him (Kosslyn & Koenig, 1992).

TWO ARE BETTER THAN ONE: WORDS AND IMAGES. Allan Paivio's (1986, 2006; J. M. Clark & Paivio, 1991) **dual coding theory** suggests that information is stored in long-term memory as either visual images or verbal units, or both. Psychologists who agree with this point of view believe that information coded both visually and verbally is easiest to learn (Butcher, 2006). This may be one reason why explaining an idea with words and then representing it visually in a figure, as we do in textbooks, has proved helpful to students (Eitel & Scheiter, 2015).

STOP & THINK What makes a cup a cup? List the characteristics of *cupness*. What is a fruit? Is a banana a fruit? Is a tomato a fruit? How about a squash? A watermelon? A sweet potato? An olive? A coconut? How did you learn what makes a fruit a fruit? •

Teaching Concepts (II, A2)

Teachers devote much effort to the development of concepts that are vital in learning subject matter and skills. Understand the major approaches to teaching concepts and be able to describe their strengths and limitations.

Dual coding theory

Suggests that information is stored in long-term memory as either visual images or verbal units, or both.

Concept A category used to group similar events, ideas, objects, or people.

Defining attribute

Qualities that connect members of a group to a specific concept.

Prototype A best example or best representative of a category.

CONCEPTS. Most of what we know about cups and fruits and the world involves concepts and relations among concepts (Eysenck, 2012; Radvansky & Ashcraft, 2014). But what exactly is a concept? A **concept** is a mental representation used to group similar events, ideas, objects, or people into a category. When we talk about a particular concept such as *student*, we refer to our mental representation of a category of people who are similar to one another: they all study a subject. The people may be old or young, in school or not; they may be studying basketball or Bach, but they all can be categorized as students. Concepts are abstractions. They do not exist in the real world. Only individual examples of concepts exist. Concepts help us organize vast amounts of information into manageable units. For instance, there are about 7.5 million distinguishable differences in colors. By mentally categorizing these colors into some dozen or so groups, we manage to deal with this diversity quite well (Bruner, 1973).

In early research, psychologists assumed that people create concepts based on rules about **defining attributes**, or distinctive features. Your concept of a cat might include defining attributes such as a round head on a small body, triangle-shaped ears, whiskers, four legs, and fur. This concept enables you to identify cats whether they are calico or Siamese without relearning “cat” each time you encounter a new cat. The defining attributes theory of concepts suggests that we recognize specific examples by noting key required features.

Since about 1970, however, these views about the nature of concepts have been challenged (Radvansky & Ashcraft, 2014). Although some concepts, such as equilateral triangle, have clear-cut defining attributes, most concepts do not. Take the concept of *party*. What are the defining attributes? You might have difficulty listing these attributes, but you probably recognize a party when you see or hear one (unless, of course we are talking about political parties, or the other party in a lawsuit, where the sound might not help you recognize the *party*). What about the concept of *bird*? Your first thought might be that birds are animals that fly. But is an ostrich a bird? What about a penguin? A bat?

PROTOTYPES, EXEMPLARS, AND THEORY-BASED CATEGORIES. One current view of concept learning suggests that we have in our minds a prototype of a party or a bird or the letter *A*—an image that captures the essence of each concept. A **prototype** is the best representative of its category—an example that has the most important “core” features of the category. For instance, the best representative of the “birds” category for many North Americans might be a robin (Rosch, 1973). Other members of the category may be very similar to the prototype (sparrow) or similar in some ways but different in

others (chicken, ostrich). At the boundaries of a category, it may be difficult to determine if a particular instance really belongs. For example, is a television “furniture”? Is an elevator a “vehicle”? Is an olive a “fruit”? Whether something fits into a category is a matter of degree or graded membership. Thus, categories have fuzzy boundaries. Some events, objects, or ideas are simply better examples of a concept than others (Eysenck, 2012; Radvansky & Ashcraft, 2014).

Another explanation of concept learning suggests that we identify members of a category by referring to exemplars. **Exemplars** are our actual memories of specific birds, parties, furniture, and so on that we use to compare with an item in question to see if that item belongs in the same category as our exemplar. Prototypes probably are built from experiences with many exemplars. This happens naturally because memories of particular events (episodic memories) tend to blur together over time, creating for example an average or typical sofa *prototype* from all the sofa *exemplars* you have experienced (E. E. Smith & Kosslyn, 2007).

There are some drawbacks to prototype and exemplar theories. For example, how do you know which “bird experiences” to blur or average together to create a bird concept if you don’t already have a bird concept? One answer is that our classifications are essentially **theory-based** ideas about the world that we create to make sense of things. So a *brick*, a *rock*, and a *shoe* are in the same category if the category is “things to pound a nail with if I don’t have a hammer.” Our theory of what might work creates the “things to pound with” category. Some of the knowledge used to create concepts based on theories may be implicit and out-of-awareness, for example, what makes for “good music”—I just know it when I hear it (Radvansky & Ashcraft, 2014; Sternberg & Sternberg, 2012).

Jacob Feldman (2003) suggests a final aspect of concept formation—the simplicity principle. Feldman says that when humans are confronted with examples, they induce the simplest category or rule that would cover all the examples. Sometimes it is easy to come up with a simple rule (triangles), and sometimes it is more difficult (fruit), but humans seek a simple hypothesis for collecting all the examples under one concept. Feldman suggests that this simplicity principle is one of the oldest ideas in cognitive psychology: “organisms seek to understand their environment by reducing incoming information to a simpler, more coherent, and more useful form” (p. 231). Does this remind you of the Gestalt principles of perception?

TEACHING CONCEPTS. In teaching concepts, provide the name of the concept and a definition, but don’t stop there. Students also need a description of relevant and irrelevant attributes as well as examples and nonexamples. They need guidance in finding the “fuzzy edges” of the concept. Make sure some examples are *prototypes*—the most obvious members of the concept category (robin or sparrow for birds; apple or orange for fruit). Also include examples near the fuzzy edges (ostrich or penguin for birds; olive or tomato for fruit). Present both concrete and abstract examples, such as using manipulatives in math to solve word problems, then connecting the answers found using these concrete materials to abstract numbers and formulas that also solve the problem. Point out how the specific relates to the abstract (Pashler, 2007). See Table 8.2 on the next page for a summary of how to teach the concept of “chair.” Of course, this is not the “chair” of a department or an endowed “chair” professorship or “chairing” a meeting—even seemingly simple concepts can be confusing if your first language is not English.

To practice the concept, have students sort items into examples or nonexamples and then explain to partners why they made their choices. Also, have students place the concepts into larger networks of knowledge called *schemas*.

SCHEMAS. Propositions, concepts, and single images are fine for representing single ideas and simple relationships, but often our knowledge about a topic combines many concepts, images, and propositions. To explain this kind of complex knowledge, psychologists developed the idea of a schema. **Schemas** (sometimes called *schemata*) are abstract knowledge structures that organize vast amounts of information. A schema (the singular form) is a mental framework that guides our perception and helps us make

Exemplar An actual memory of a specific object.

Theory-based An explanation for concept formation that suggests our classifications are based on ideas about the world that we create to make sense of things.

Schemas (singular, schema) In cognitive theory, basic structures for organizing information; concepts.

TABLE 8.2 • Teaching the Concept of Chair

Here are key elements to use in teaching about chairs

TEACHING STEP	EXAMPLE
Name concept	Chair
Define concept	Seat with a back for one person
Describe relevant (defining) attributes	Seat, back
Describe irrelevant attributes	Legs, size, color, material, design
Give examples	Easy chair, dining table chair, recliner, beanbag chair, high chair, desk chair (fuzzy examples: airplane seat? Movie seat?)
Give nonexamples	Bench, stool, table, sofa

Source: Based on Schunk, D. H. (2016). *Learning Theories: An Educational Perspective* (7th ed.). Boston, MA: Allyn & Bacon/Pearson, p. 258.

sense of our experience based on what we already know and what we expect to happen (Sternberg & Sternberg, 2012). Figure 8.5 is a partial representation of a schema for knowledge about reinforcement.

The schema tells you what features are typical of a category, what to expect about an object or situation. The pattern has “slots” that are filled with specific information as we apply the schema in a particular situation. And schemas are personal. For example, my schema of *reinforcement* is less richly developed than Skinner’s schema must have been. You encountered a very similar concept of *schemes* (organized systems of action and thought) in the discussion of Piaget’s theory of cognitive development in Chapter 2.

FIGURE 8.5

A PARTIAL SCHEMA FOR REINFORCEMENT

The concept of *reinforcement* is under the general category of *consequence*. It is related to other concepts such as eating in restaurants or bouncing babies, depending on the individual’s experiences.

When you hear the sentence, “Lincoln, who was president of the United States during a bitter war, freed the slaves,” you know even more than the three propositions. You probably can infer that reuniting the country after the war was difficult based on your schema for a “bitter” conflict. Your schema for “slaves” gives you some sense of the kind of life they were freed from. None of this information was explicitly stated in the sentence.

Schematic knowledge helps us to form and understand concepts. How do we know that counterfeit money is not “real” money, even though it perfectly fits our “money” prototype and exemplars and looks like real money? We know because of its history. The “wrong” people printed the money. So our understanding of the concept of money is connected with concepts of crime, forgery, the federal treasury, and many others in a larger schema for “money.”

Another type of schema, a **story grammar** (sometimes called a *schema for text* or *story structure*), helps students to understand and remember stories. A specific story grammar for murder mysteries could be something like this: murder discovered, search for clues, murderer’s fatal mistake identified, trap set to trick suspect into confessing, murderer takes bait . . . mystery solved! To comprehend a story, we select a schema that seems appropriate. Then, we use this framework to decide which details are important, what information to seek, and what to remember. It is as though the schema is a theory about what should occur in the story. The schema guides us in “interrogating” the text, pointing to the specific information we expect to find so that the story makes sense. If we activate our “murder mystery schema,” we may be alert for either clues or a murderer’s fatal mistake. Without an appropriate schema, trying to understand a story, textbook, or classroom lesson is a very slow, difficult process, something like finding your way through a new town without a map or GPS. And because there are cultural differences in schemas, it is possible that students bring different schemas to reading and therefore “read” different meanings into the same text. The meaning is not simply in the text; it is in the reader’s interpretation based on the schemas he or she used to make sense of the text (Lee, 2016).

Propositions, images, concepts, and schemas are all explicit *semantic* memories. The second kind of explicit memory is *episodic*.

EPISODIC MEMORY. Memory for information tied to a particular place and time, especially information about the events or episodes of your own life, is called **episodic memory**. Episodic memory is about events we have experienced, so we often can explain when the event happened. In contrast, we usually can’t describe when we acquired a semantic memory. For example, you may have a difficult time remembering when you developed semantic memories for the meaning of the word *injustice*, but you can easily remember a time that you felt unjustly treated. Episodic memory also keeps track of the order of things, so it is a good place to store jokes, gossip, or plots from films.

Memories for dramatic or emotional moments in your life are called **flashbulb memories**. These memories are vivid and complete, as if your brain demanded that you “record this moment.” Under stress, more glucose energy goes to fuel brain activity, while stress-induced hormones signal the brain that something important is happening (Myers, 2005; Sternberg & Sternberg, 2012). So when we have intense emotional reactions, memories are stronger and more lasting. Many people have vivid memories of very positive or very negative events in school such as winning a prize or being humiliated. People over 60 have vivid memories of the day John Kennedy was assassinated. My whole school had walked to the main street of our suburb of Fort Worth, Texas, to applaud as his motorcade drove by en route to the airport for the flight to Dallas. By the time I got back to geometry class, we heard the announcement that he had been shot in Dallas. My friend, who had been at a press breakfast with him that very morning, was devastated.

Contents of Long-Term Memory: Implicit Memories

Look back at Figure 8.4. You will see that there are three kinds of implicit, or unconscious, memories: *classical conditioning*, *procedural memory*, and *priming effects*. In classical conditioning, as we saw in Chapter 7, some unconscious memories may cause you to feel anxious as you take a test or make your heart rate increase when you hear a dentist’s drill or a siren.

Story grammar Typical structure or organization for a category of stories.

Episodic memory Long-term memory for information tied to a particular time and place, especially memory of the events in a person’s life.

Flashbulb memories Clear, vivid memories of emotionally important events in your life.

FIGURE 8.6

A CHILD'S SCRIPT FOR A FAST-FOOD RESTAURANT

The second type of implicit memory is **procedural memory** for skills, habits, and how to perform tasks—in other words, memory for procedural knowledge. It may take a while to learn a procedure such as how to ski, factor an equation, or design a teaching portfolio, but once learned, this knowledge tends to be remembered for a long time. Procedural knowledge is represented as *scripts* and *productions*.

Scripts are action sequences or plans for actions stored in memory (Schraw, 2006). We all have scripts for events like ordering food in restaurants, and these scripts differ depending on whether the restaurant is a four-star bistro or a fast-food drive-through. Even young children have scripts for how to behave during snack time at preschool, or at a friend's birthday party, or in a restaurant, as you can see in Figure 8.6. In fact, for very young children, scripts seem to help them organize and remember the predictable aspects of their world. This frees up some working memory to learn new things and recognize when something is out of place in the situation. In terms of human survival, it probably is useful to remember what should happen and to notice when something seems out of place (K. Nelson & Fivush, 2004).

Productions specify what to do under certain conditions: If A occurs, then do B. A production might be something like, “If you want to snow ski faster, lean back slightly,” or “If your goal is to increase student attention and a student has been paying attention a bit longer than usual, then praise the student.” People can’t necessarily state all their scripts and productions, and they don’t even realize that they are following these rules, but they act on them nevertheless. The more practiced the procedure, the more automatic the action and the more implicit the memory (J. R. Anderson, 2015; Schraw, 2006).

Connect and Extend to PRAXIS II®

Memory and Recall (I, A1)

Cognitivists emphasize the role that elaboration, organization, and context have in effective encoding of information into long-term memory. Be aware of techniques that make use of those processes.

Procedural memory Long-term memory for how to do things.

Script Schema, or expected plan, for the sequence of steps in a common event such as buying groceries or ordering pizza.

Productions The contents of procedural memory; rules about what actions to take, given certain conditions.

Priming Activating a concept in memory or the spread of activation from one concept to another.

STOP & THINK Fill in these blanks: MEM _ _ _ •

The final type of implicit memory involves **priming**, or activating information that already is in long-term memory through some out-of-awareness process. You might have seen an example of priming in the *Stop & Think* fill-in-the-blank question. If you wrote MEMORY instead of MEMOIR or MEMBER, or other MEM words, then priming may have played a role because the word *memory* has occurred many times in this chapter. Priming may be the fundamental process for retrieval as associations are activated and spread through the memory system (Radvansky & Ashcraft, 2014).

Retrieving Information in Long-Term Memory

The final section of this chapter will examine in depth what you have to do to “save” information permanently—to create explicit and implicit memories. Here we consider some general ideas about retrieving and forgetting information from long-term memory. When we need to use information from long-term memory, we search for it. Sometimes, the search is conscious, as when you see a friend approaching and search for her name. At other times, locating and using information from long-term memory is automatic, as when you enter a computer password or the word *memory* pops to mind when you see MEM _ _ . Think of long-term memory as a huge cabinet full of tools (skills, procedures) and supplies (knowledge, concepts, schemas) ready to be brought to the workbench of working memory to accomplish a task. The cabinet (long-term memory)

stores an incredible amount, but it may be hard to find what you are looking for quickly. The workbench (working memory) is small, but anything on it is immediately available. Because it is small, however, supplies (bits of information) sometimes are lost when the workbench is overloaded or when one bit of information covers (interferes with) another (E. Gagné, 1985). Of course you have to walk into the room through the door of attention to get to the workbench and the cabinet (Silverman, 2008).

SPREADING ACTIVATION. The size of the network in long-term memory is huge, but only small parts are activated at any one time—in fact, as you saw earlier, some psychologists say the smaller activated part of long-term memory *is* working memory. Information is retrieved in this network through **spreading activation**. When a particular proposition or image is active—when we are thinking about it—other closely associated knowledge can be primed or triggered as well, and activation can spread through the network (J. R. Anderson, 2015). Thus, as I focus on the propositions, “I’d like to go for a drive to see the fall leaves,” related ideas such as, “I should rake leaves,” and “The car needs an oil change,” come to mind. As activation spreads from the “car trip” to the “oil change,” the original thought, or active memory, disappears from working memory because of the limited space. Thus, **retrieval** from long-term memory occurs partly through the spreading of activation from one bit of knowledge to related ideas in the network.

RECONSTRUCTION. In long-term memory, the information is still available, even when it is not activated and you are not thinking about it at the moment. If spreading activation does not “find” the information we seek, then we might still come up with an answer through **reconstruction**, a cognitive tool or problem-solving process that makes use of logic, cues, and other knowledge to construct a reasonable answer by filling in any missing parts (Koriat, Goldsmith, & Pansky, 2000). Sometimes reconstructed recollections are incorrect. For example, in 1932, F. C. Bartlett conducted a series of famous studies on remembering stories. He read a complex, unfamiliar Native American tale to students at England’s Cambridge University and, after various lengths of time, asked the students to recall the story. Stories the students recalled were generally shorter than the original and were translated into the concepts and language of the Cambridge student culture. The story told of a seal hunt, for instance, but many students remembered (reconstructed) a “fishing trip,” an activity closer to their experiences and more consistent with their schemas.

FORGETTING AND LONG-TERM MEMORY. Over 100 years ago, Hermann Ebbinghaus (1885/1964), a pioneer in studying memory for verbal information, said simply, “All sorts of ideas, if left to themselves, are gradually forgotten. This fact is generally known” (p. 62). Information appears to be lost from long-term memory through time decay and interference. For example, memory for Spanish–English vocabulary decreases for about 3 years after a person’s last course in Spanish, then stays level for about 25 years, then drops again for the next 25 years. One explanation for this decline is that neural connections, like muscles, grow weak without use. After 25 years, it may be that the memories are still somewhere in the brain, but they are too weak to be reactivated. Also, the physiological deterioration that comes with age could account for the later declines because some neurons simply die (J. R. Anderson, 2015). Finally, newer memories may interfere with or obscure older memories, and older memories may interfere with memory for new material.

Even with decay and interference, long-term memory is remarkable. Information in working memory can be lost and forgotten, but information stored in long-term memory may be available for a long time, given the right cues (Erdelyi, 2010). Teaching strategies that encourage student engagement, deeper processing of information, and higher levels of initial learning are associated with longer retention. Some example strategies are:

- Frequent reviews and tests
- Elaborated feedback
- High standards
- Mastery learning
- Active involvement in learning projects

Spreading activation Retrieval of pieces of information based on their relatedness to one another. Remembering one bit of information activates (stimulates) recall of associated information.

Retrieval Process of searching for and finding information in long-term memory.

Reconstruction Recreating information by using memories, expectations, logic, and existing knowledge.

Individual Differences in Long-Term Memory

The major individual difference that affects long-term memory is knowledge. As we saw earlier with the fourth-grade soccer experts, when people have more domain-specific declarative and procedural knowledge, they are better at learning and remembering material in that domain (Schunk, 2016). Think about what it is like to read a very technical textbook in an area you know little about. Every line is difficult. You have to stop and look up words or turn back to earlier sections to read about concepts you don't understand. It is hard to remember what you are reading because you are trying to understand and remember at the same time. But with a good basis of knowledge, learning and remembering become easier; the more you know, the easier it is to know more. This may be why classes in your major seem easier than the required classes outside your major. Another factor could be interest. To develop expert understanding and recall in a domain requires the “continuous interplay of skill (i.e., knowledge) and thrill (i.e., interest)” (Alexander, Kulikowich, & Schulze, 1994, p. 334).

Now let's turn to the really important question: How can teachers support the development of long-lasting knowledge?

MyLab Education [Self-Check 8.3](#)

TEACHING FOR DEEP, LONG-LASTING KNOWLEDGE: BASIC PRINCIPLES AND APPLICATIONS

How can we make the most effective use of our practically unlimited capacity to learn and remember? For decades, cognitive psychologists have focused on ways of constructing long-lasting declarative, procedural, and self-regulatory knowledge. We will discuss the development of *declarative* and *procedural* knowledge separately, but keep in mind that real learning is a combination and integration of these elements. We look at developing the third type, *self-regulatory* knowledge, in the next chapter when we discuss metacognition.

Constructing Declarative Knowledge: Making Meaningful Connections

We begin with some basic principles that apply across all situations. The way you learn information in the first place strongly affects its recall later. One important requirement for building lasting knowledge is that you integrate new information with your prior knowledge—what you already know—as you construct an understanding. Here, *elaboration*, *organization*, *imagery*, *context*, *desirable difficulty*, and *effective practice* play important roles.

ELABORATION. Adding meaning to new information by connecting with already existing knowledge is called **elaboration**. In other words, we apply our schemas and draw on already existing knowledge to construct an understanding. Frequently, we change our existing knowledge in the process, as Piaget noted years ago. We often elaborate automatically. For example, a paragraph about an historic figure in ancient Rome tends to activate our existing knowledge about that period; we use the old knowledge to understand the new.

Material that is elaborated when first learned will be easier to recall later. First, as we saw earlier, elaboration is a form of rehearsal that leads to deeper levels of processing because the information is thoroughly analyzed and connected with existing information (Craik & Tulving, 1975). Second, elaboration builds extra links to existing knowledge. The more one bit of information or knowledge is associated with other bits, the more routes there are to follow to get to the original bit. To put it another way, you have several “handles” or priming/retrieval cues to “pick up” or recognize the information you might be seeking (Bruning et al., 2011).

Elaboration Adding and extending meaning by connecting new information to existing knowledge.

GUIDELINES

FAMILY AND COMMUNITY PARTNERSHIPS

Organizing Learning

Give families specific strategies to help their children practice and remember.

Examples

1. Develop “super learner” homework assignments that include material to be learned and a “parent coaching card” with a description of a simple memory strategy—appropriate for the material—that parents can teach their child.
2. Provide a few comprehension check questions so a family member can review reading assignments and check the child’s understanding.
3. Describe the value of distributed practice, and give family members ideas for how and when to work skills practice into home conversations and projects.

Ask family members to share their strategies for organizing and remembering.

Examples

1. Create a family calendar.
2. Encourage planning discussions in which family members help students break large tasks into smaller jobs, identify goals, and find resources.

Discuss the importance of attention in learning.

Examples

1. Encourage families to create study spaces that are away from distractions.
2. Make sure parents know the purpose of homework assignments.

For a Web site dedicated to high school study skills that might help parents, see mtsu.edu and search for study skills.

The more students elaborate new ideas, the more they “make them their own,” the deeper their understanding and the better their memory for the knowledge will be. Learning is improved when students have to *create their own answers* rather than just recognize or recall answers from the textbook or the teacher (Brown, Roediger, & McDaniel, 2014). We help students to elaborate and create when we ask them to:

- translate into their own words
- create examples
- explain to a peer
- create a metaphor
- draw a diagram of the situation
- act out the relations
- apply the information to new problems

Of course, if students elaborate new information by developing misguided explanations, these misconceptions will be remembered, too, so teacher guidance, feedback, and frequent testing are critical.

ORGANIZATION. A second element of processing that improves learning is **organization**. Material that is well organized is easier to learn and to remember than bits and pieces of information, especially if the material is complex or extensive. Chunking is one kind of organization—putting small bits of information into larger, more meaningful chunks. Placing a concept in a structure also will help you learn and remember both general definitions and specific examples. The structure serves as a guide back to the information when you need it. For example, Table 8.1 organizes information about types of cognitive load and Figure 8.5 organizes my knowledge about reinforcement. The *Guidelines: Family and Community Partnerships* give ideas for working with families to provide all your students more support and practice in organizing learning.

IMAGERY. You may remember that the dual coding theory of memory suggests that information coded both visually and verbally is easiest to learn (Butcher, 2006; Paivio, 2006). Imagery can support memory if the information to be learned lends itself to

Organization Ongoing process of arranging information and experiences into mental systems or categories. Ordered and logical network of relations.

images. It is easier to form an image for *car* than for *internal combustion*, for example—at least for me. Also the ability to form and use mental images appears to vary among individuals; some people are simply better at this task than others (Bruning et al., 2011).

That said, is a picture worth a thousand words in teaching? Richard Mayer (2001, 2005, 2011) has studied this question for several years and has found that the right combination of pictures and words can make a significant difference in students' learning, at least for older students. Mayer's cognitive theory of multimedia learning includes three ideas that should be familiar to you now:

- **Dual coding:** Visual and verbal materials are processed in different systems (Clark & Paivio, 1991).
- **Limited capacity:** Working memory for verbal and visual material is severely limited. Cognitive load has to be managed (Baddeley, 2001; van Merriënboer & Sweller, 2005).
- **Generative learning:** Meaningful learning happens when students focus on relevant information and generate or build connections (Mayer, 2008, 2011).

The problem: How to build complex understandings that integrate information from visual (pictures, diagrams, graphs, animations, films) and verbal (text, lecture) sources, given the limitations of working memory. **The solution:** Make sure the information is available at the same time or in focused small bites. Mayer and Gallini (1990) provide an example. They used three kinds of texts to explain how a bicycle pump works. One text used only words, the second had pictures that just showed the parts of the pump system and the steps, and the third (this one improved student learning and recall) showed both the “on” and the “off” states of the pumps with labels right on the illustration for each step in the pumping process, as you can see in Figure 8.7.

FIGURE 8.7

DO IMAGES AND WORDS HELP STUDENTS UNDERSTAND?

Is a picture worth a thousand words in teaching? The right combination of pictures and words, like the labeled illustrations here, can make a significant difference in college students' learning, but these illustrations were not as successful with middle schoolers. What would support their learning from words and pictures?

Source: Based on Mayer and Gallini (1990).

There is a caution about using multiple representations to teach, however. The students in Mayer's studies were in college. When Erin McTigue (2009) tried to replicate these kinds of results with middle school students in life and physical sciences, the labeled pictures led to small improvements in students' understanding for life science texts, but not for physical science texts. So research has shown that just using multiple representations (words, pictures, diagrams, charts, animations, etc.) does not necessarily lead to better learning. Students, especially younger ones, need supports such as color coding to draw attention to relevant relations in pictures and diagrams, or frequent checks for understanding—with corrections if they are forming misconceptions (Berthold & Renkl, 2009). The moral of the story? Give students multiple ways to understand—pictures and explanations. But don't overload working memory—"package" the visual and verbal information together in bite-size (or memory-size) pieces, and teach students directly how to learn from illustrations or how to draw their own.

CONTEXT. A fourth element of processing that influences learning is **context**. Aspects of physical and emotional context—places, rooms, moods, who is with us—are learned along with other information. Later, if you try to remember the information, it will be easier if the current context is similar to the original one (Radvansky & Ashcraft, 2014). Context is a kind of priming that activates the information. For example, in a classic study, scuba divers who learned a list of words underwater and then were tested underwater remembered more than scuba divers who learned underwater but were tested on dry land (Godden & Baddeley, 1975). In another study, students who learned material in one type of room performed better on tests taken in a similar room than they did on comparable tests taken in a very different-looking room (S. M. Smith, Glenberg, & Bjork, 1978). So, studying for a test under "test-like" conditions (e.g., not at McDonald's) may result in improved performance. Of course, you can't always go back to the same place or a similar one to recall something. But if you can picture the setting, the time of day, and your companions, you may eventually reach the information you seek.

DESIRABLE DIFFICULTY. A fifth element of processing is **desirable difficulty**. It seems like a paradox, but the more effort that is required to remember something (which really means you are *relearning* the information), the better you will learn and the stronger the memory will be—as long as the efforts are successful, of course. It may take longer to learn, but long-term recall is stronger and faster. Desirable difficulty leads to deep processing. Here is a surprising example. When the outline of a lecture varies from the outline of the reading for the lecture, memory for the main ideas is better. One reason is that the effort needed to figure out the main ideas and integrate and reconcile the two different explanations of the same material helps the learners understand the ideas better and make them their own (Brown et al., 2014). When students breeze through readings or answer questions that are too easy, they may get the illusion that they know the content—it all seems so obvious. But without the text, the knowing proves fragile. The students can't really explain the material in their own words.

EFFECTIVE PRACTICE. One of the best ways to learn and remember is through **retrieval practice**, often called the **testing effect**. Research on learning repeatedly shows that practicing by retrieving information is more effective than just restudying or rereading. Repeated recall seems to help memories consolidate in the brain, and it strengthens the neural pathways so the knowledge is easier to find later. As Peter Brown and his colleagues (2014) said, "retrieval ties the knot for memory. Repeated retrieval snugs it up and adds a loop to make it fast" (p. 28).

Here is another kind of effective practice. Would you predict that children who practiced tossing beanbags into a bucket from 3 feet away would be better or worse at accurate tosses from 3 feet compared to children who practiced from 2 feet and 4 feet, but never from 3 feet? Surprisingly, the children who practiced only from 3 feet were worse (Brown et al. 2014). **Interleaved practice** is mixing up practice by, for example, tossing from 2 and 4 feet before being tested at 3 feet. (Does this mean that basketball

Context Internal and external circumstances and situations that interact with the individual's thoughts, feelings, and actions to shape development and learning. The physical or emotional backdrop associated with an event.

Desirable difficulty The more effort that is required to remember something, the better you will learn and the stronger the memory will be—as long as the efforts are successful.

Retrieval practice/testing effect Practicing by retrieving information from memory instead of rereading or restudying—more effective because retrieval seems to help memories consolidate in the brain and strengthens the neural pathways so the knowledge is easier to find later.

Interleaved practice Mixing up practice by, for example, tossing from 2 and 4 feet before being tested at 3 feet, solving different types of problems, or practicing different vocabulary words.

players should practice free throws from different distances—an interesting question!). Another example is doing homework that requires applying different strategies for solving math problems. Instead of having every problem solved by calculating a proportion or applying the Pythagorean theorem, mix up types of problems so students have to both decide on the strategy they must use to solve the problem *and then* also apply that strategy. This makes practice more like real life where you have to decide what the actual question is and then answer it (Rohrer, Dedrick, & Stershic, 2015).

We can incorporate many of these strategies by making each lesson as meaningful as possible.

Reaching Every Student: Make it Meaningful

Meaningful lessons are presented in vocabulary that makes sense to the students. New terms are clarified through ties with more familiar words and ideas. Meaningful lessons are well organized, with clear connections between the different elements of the lesson. Finally, meaningful lessons make natural use of old information to help students understand new information through examples or analogies.

The importance of meaningful lessons is emphasized in *Stop & Think*—an example presented years ago by F. Smith (1975).

STOP & THINK Look at the three lines below. Begin by covering all but the first line. Look at it for a second, close the book, and write down all the letters you remember. Then repeat this procedure with the second and third lines.

1. KBVODUWGPJMSQTXNOGMCTRSO
2. READ JUMP WHEAT POOR BUT SEEK
3. KNIGHTS RODE HORSES INTO WAR •

Each line has the same number of letters, but the chances are great that you remembered all the letters in the third line, a good number of letters in the second line, and very few in the first line. The first line makes no sense. There is no way to organize it in a brief glance. Working memory is simply not able to hold and process all those bits of information quickly. The second line is more meaningful. You do not have to see each letter because your long-term memory brings prior knowledge of spelling rules and vocabulary to the task. The third line is the most meaningful. Just a glance and you can probably remember all of it because you bring to this task prior knowledge not only of spelling and vocabulary but also of rules about syntax and probably some historical information about knights (they didn't ride in tanks). This sentence is meaningful because you have existing schemas for assimilating it (Sweller, van Merriënboer, & Paas, 1998).

The challenge for teachers is to make lessons less like learning the first line and more like learning the third line. Although this may seem obvious, think about the times when you have read a sentence in a text or heard an explanation from a professor that might just as well have been KBVODUWGPJMSQTXNOGMCTRSO. But beware, attempts to change the ways that students are used to learning—moving from memorizing to meaningful—are not always greeted with student enthusiasm. Students may be concerned about their grades; at least when memorization gains an A, they know what is expected. Meaningful learning can be riskier and more challenging. In Chapters 9, 10, and 11, we will examine a variety of ways in which teachers can support meaningful learning and understanding.

What can you do when students don't have a good base of knowledge? Mnemonics is a memory strategy for getting started.

MNEMONICS. Mnemonics are systematic procedures for improving memory (Rummel, Levin, & Woodward, 2003; Soemer & Schwan, 2012). When information has little inherent meaning, mnemonic strategies help to create meaning by connecting what is to be learned with established words or images.

Connect and Extend to PRAXIS II®

Prior Knowledge (I, A1)

Prior knowledge strongly influences how we build and reorganize new knowledge. Be familiar with the role of schemas and propositional networks in the construction of knowledge and how they affect learning.

Mnemonics Techniques for remembering; the art of memory.

The **loci method** derives its name from the plural of the Latin word *locus*, meaning “place.” To use loci, you must first imagine a very familiar place, such as your own house or apartment, and pick out particular locations to serve as “pegs” to “hang” memories. For instance, let’s say you want to remember to buy milk, bread, butter, and cereal at the store. Imagine a giant jug of milk blocking the entry hall, a lazy loaf of bread sleeping on the living room couch, a stick of butter melting all over the dining room table, and cereal covering the kitchen floor. When you want to remember the items, all you have to do is take an imaginary walk through your house.

If you need to remember information for long periods of time, an acronym may be the answer. An **acronym** is a form of abbreviation—a word formed from the first letter of each word in a phrase, for example, HOMES to remember the Great Lakes (Huron, Ontario, Michigan, Erie, Superior). Another method forms phrases or sentences out of the first letter of each word or item in a list, for example, Every Good Boy Does Fine to remember the lines on the G clef—E, G, B, D, F. Because the words must make sense as a sentence, this approach also has some characteristics of **chain mnemonics**, methods that connect the first item to be memorized with the second, the second item with the third, and so on. In one type of chain method, each item on a list is linked to the next through some visual association or story. Another chain-method approach is to incorporate all the items to be memorized into a jingle such as “i before e except after c.”

The mnemonic system that has been most extensively researched in teaching is the **keyword method**. Joel Levin and his colleagues use a mnemonic (the 3 Rs) to teach the keyword mnemonic method:

- **Recode** the to-be-learned vocabulary item as a more familiar, concrete keyword—this is the keyword.
- **Relate** the keyword clue to the vocabulary item’s definition through a sentence.
- **Retrieve** the desired definition.

The keyword method has been used extensively in foreign language learning. For example, the Spanish word *carta* (meaning “letter”) sounds like the English word *cart*. *Cart* becomes the keyword: You imagine a shopping cart filled with letters on its way to the post office, or you make up a sentence such as “The cart full of letters tipped over.” A similar approach has been used to help students connect artists with particular aspects of their paintings. For example, students are told to imagine that the heavy dark lines of paintings by Rouault are made with a *ruler* (Rouault) dipped in black paint (Carney & Levin, 2000, 2002).

Vocabulary learned with keywords can be easily forgotten if students are given keywords and images instead of being asked to supply words and images that are relevant to them. When the teacher provides the memory links, these associations may not fit the students’ existing knowledge and may be forgotten or confused later; as a result, remembering suffers (Wang & Thomas, 1995; Wang, Thomas, & Ouellette, 1992). Younger students have some difficulty forming their own images. For them, memory aids that rely on auditory cues—rhymes such as “Thirty days hath September” seem to work better (Willoughby, Porter, Belsito, & Yearsley, 1999). Until learners have some knowledge to guide their learning, it may help to use some mnemonic approaches to build vocabulary and facts.

The greatest challenge teachers face is to help students think and understand, not just memorize. Unfortunately, many students view **rote memorization** and learning as the same thing. Still, there are times when memorization is useful for learning new information that has little meaning at first.

If You Have to Memorize . . .

Every discipline has its own terms, names, facts, and rules. As adults, we want to work with physicians who have memorized the correct drugs needed to combat particular infections. Of course, they can look up some information or research certain conditions, but they have to know where to start. We want to work with accountants who give us

MyLab Education Video Example 8.4

Students use many different study strategies and feel confident in their choices, but not all of these strategies have a solid research base to suggest that they are effective for long-term learning.

Connect and Extend to PRAXIS II®

Memory Strategies (II, A1)

Medical students often use mnemonics to remember the vast amounts of information they encounter in their studies. Be familiar with the major mnemonic methods and the kinds of information that they are most suitable for.

Loci method Technique of associating items with specific places.

Acronym Technique for remembering by using the first letter of each word in a phrase to form a new, memorable word.

Chain mnemonics Memory strategies that associate one element in a series with the next element.

Keyword method System of associating new words or concepts with similar-sounding cue words and images.

Rote memorization Remembering information by repetition without necessarily understanding the meaning of the information.

accurate information about the new tax codes, information they probably had to memorize because it changes from year to year in ways that are not necessarily rational or meaningful. We want to deal with computer salespeople who have memorized their stock and know exactly which printers will work with our computer. Just because something was learned through memorization does not mean it is superficial or unimportant knowledge. The real question is whether you can *use* the information flexibly and effectively to solve new problems.

Sometimes memorizing is a necessary and effective strategy. For example, Alvin Wang, Margaret Thomas, and Judith Ouellette (1992) compared learning Tagalog (the national language of the Philippines) using either rote memorization or the keyword approach for associating new words with existing words and images. In their study, even though the keyword method led to faster and better learning initially, long-term forgetting was *greater* for students who had used the keyword method than for students who had learned by rote memorization. In addition, on rare occasions we even have to memorize something word for word, such as lines in a song, poem, or play. How would you do it? If you have tried to memorize a list of items that are all similar to one another, you may have found that you tended to remember items at the beginning and at the end of the list, but forgot those in the middle. This is called the **serial-position effect**. **Part learning**, breaking the list into smaller segments, can help prevent this effect, because breaking a list into several shorter lists means there will be fewer middle items to forget.

Another strategy for learning a long selection or list is the use of **distributed learning/practice**, something educational psychologists have known about since the late 1880s (Ebbinghaus, 1885/1964). A student who studies Hamlet's soliloquy intermittently throughout the week will probably do much better than a student who tries to memorize the entire speech on Sunday night. Studying for an extended period is called *massed practice*. **Massed practice** leads to cognitive overload, fatigue, and lagging motivation. Distributed or spaced learning/practice gives time for deeper processing and strengthens the connections in the neural network of the brain. What is forgotten after one session can be relearned in the next with distributed practice (Agarwal, Bain, & Chamberlain, 2012; Karpicke & Grimaldi, 2012; Pashler et al., 2007; Son & Simon, 2012). Be warned, however, research has consistently shown that even though *distributed practice* leads to better learning and remembering, students (including adults) prefer *massed practice*—another example that what we like best (I'm thinking nachos dripping with cheese and jalapeños for a late night snack) may not be best for us.

To incorporate distributed learning into your classes, make sure students are exposed to key concepts, terms, and skills on at least two occasions separated by several weeks or even months, and use homework and exams to promote spaced review. *Interleave practice* by sprinkling skills from earlier units into current homework and tests. Students get needed spaced learning and practice and also the motivation that comes with a sense of mastery—look how easy those earlier problems are now (Pashler et al., 2007). Shana Carpenter and her colleagues (2012) also recommend that teachers:

- Review important information every several weeks—keep updating these reviews with recent information.
- Re-expose students to important information in homework assignments, even several weeks after they first learned the material.
- Give exams and quizzes that are cumulative, so students will be motivated to review and space out their study sessions on their own.

Serial-position effect The tendency to remember the beginning and the end, but not the middle of a list.

Part learning Breaking a list of items into shorter lists.

Distributed learning/practice Practice in brief periods with rest intervals.

Massed practice Practice for a single extended period.

Lessons for Teachers: Declarative Knowledge

There are at least two clear lessons for teachers and teaching in the research on learning declarative knowledge. The first is the importance of connections—connecting to what the student already knows, connecting pictures and words to support understanding, connecting different specific examples of concepts to understand the abstract idea, and connecting to the context where information was first learned. The second lesson is the

power of deep processing—processing by elaborating new information, processing by forming images, processing by reviewing over time, processing by dealing with difficulty and persisting, and processing through questioning.

Development of Procedural Knowledge

One characteristic that distinguishes experts from novices in every arena, from reading to medical diagnosis, is that the experts' declarative knowledge has become "proceduralized," that is, incorporated into routines they can apply automatically without making many demands on working memory. Explicit memories have become implicit, and the expert is no longer aware of them. Skills that are applied without conscious thought are called **automated basic skills**. An example is shifting gears in a standard transmission car. At first, you have to think about every step, but as you become more expert (if you do), the procedure becomes automatic. But not all procedures can be automatic, even for experts in a particular domain. For example, no matter how expert you are in driving, you still have to consciously watch the traffic around you. This kind of conscious procedure is called a *domain-specific strategy*. Automated basic skills and domain-specific strategies are learned in different ways (Gagné, Yekovich, & Yekovich, 1993).

AUTOMATED BASIC SKILLS. Most psychologists identify three stages in the development of an automated skill: *cognitive*, *associative*, and *autonomous* (J. R. Anderson, 2015; Fitts & Posner, 1967). At the *cognitive stage*, when we are first learning, we rely on declarative knowledge and general problem-solving strategies to accomplish our goal. For example, to learn how to assemble a bookshelf, we might try to follow steps in the instruction manual, putting a check beside each step as we complete it to keep track of progress. At this stage, we have to "think about" every step and perhaps refer back to the pictures of parts to see what a "4-inch metal bolt with lock nut" looks like. The cognitive load on working memory is heavy. There can be quite a bit of trial-and-error learning at this stage when, for example, the bolt we chose doesn't fit.

At the *associative stage*, individual steps of a procedure are combined or "chunked" into larger units. We reach for the right bolt and put it into the right hole. One step smoothly cues the next. With practice (there's that word again), the associative stage moves to the *autonomous stage*, where the whole procedure can be accomplished without much attention. So if you assemble enough bookshelves, you can have a lively conversation as you do, paying little attention to the assembly task. This movement from the cognitive to the associative to the autonomous stage holds for the development of basic cognitive skills in any area, but science, medicine, chess, and mathematics have been most heavily researched. One thing is clear—it takes many hours of successful practice to make skills automatic. In addition, to become a real expert at a skill, practice must be deliberate. **Deliberate practice** means comparing your performance to a high standard, monitoring how well you are doing, seeking and using feedback, and focusing on areas that need improvement. Just repeating what you already know how to do won't make you an expert (Ericsson, 2011).

What can teachers do to help their students pass through these three stages and become more expert learners? In general, it appears that two factors are critical: *prerequisite knowledge* and *practice with feedback*. First, if students don't have the essential prior knowledge (concepts, schemas, skills, etc.), the cognitive load on working memory will be too great. Second, practice with feedback allows you to form associations, recognize cues automatically, and combine small steps into larger productions. Even from the earliest stage, some of this practice should include a simplified version of the whole process in a real context. Practice in real contexts helps students learn not only *how* to do a skill but also *why and when* (A. Collins, Brown, & Newman, 1989; Gagné, Yekovich, & Yekovich, 1993). Of course, as every athletic coach knows, if a particular step, component, or process is causing trouble, that element might be practiced alone until it becomes more automatic, and then put back into the whole sequence, to lower the cognitive load on working memory (J. R. Anderson et al., 1996; A. Ericsson, 2011).

Developing Basic Skills (II, A3)

Efficient and effective performance as a learner requires the automatic use of basic skills. Describe what teachers can do to help students develop automatic basic skills.

Automated basic skills

Skills that are applied without conscious thought.

Deliberate practice

Comparing your performance to a high standard, monitoring how well you are doing, seeking and using feedback, and focusing on areas that need improvement.

GUIDELINES

Helping Students Understand and Remember

Make sure you have the students' attention.

Examples

1. Develop a signal that tells students to stop what they are doing and focus on you. Make sure students respond to the signal—don't let them ignore it. Practice using the signal.
2. Move around the room, use gestures, and avoid speaking in a monotone.
3. Begin a lesson by asking a question that stimulates interest in the topic.
4. Regain the attention of individual students by walking closer to them, using their names, or asking them a question.

Help students separate essential from nonessential details and focus on the most important information.

Examples

1. Summarize instructional objectives to indicate what students should be learning. Relate the material you are presenting to the objectives as you teach: "Now I'm going to explain exactly how you can find the information you need to meet Objective One on the board—determining the tone of the story."
2. When you make an important point, pause, repeat, ask a student to paraphrase, note the information on the board in color, or tell students to highlight the point in their notes or readings.

Help students make connections between new information and what they already know.

Examples

1. Review prerequisites to help students bring to mind the information they will need to understand new material: "Who can tell us the definition of a quadrilateral? Now, what is a rhombus? Is a square a quadrilateral? Is a square a rhombus? What did we say yesterday about how you can tell? Today we are going to look at some other quadrilaterals."
2. Use an outline or diagram to show how new information fits with the framework you have been developing. For example, "Now that you know the duties of the FBI, where would you expect to find it in this diagram of the branches of the U.S. government?"
3. Give an assignment that specifically calls for the use of new information along with information already learned.

Space out learning and provide for repetition and review of information.

Examples

1. Begin the class with a quick review of the homework assignment.
2. Give frequent, short tests.
3. Build practice and repetition into games, or have students work with partners to quiz each other.

Present material in a clear, organized way.

Examples

1. Make the purpose of the lesson very clear.
2. Give students a brief outline to follow. Put the same outline on an overhead transparency so you can keep yourself on track. When students ask questions or make comments, relate these to the appropriate section of the outline.
3. Use summaries in the middle and at the end of the lesson.

Manage cognitive load.

Examples

1. In the beginning, eliminate details or decorations that distract from the main ideas.
2. Give students strategies for keeping up with information as they go along—mapping relationships, defining key terms, or writing one-minute summaries.
3. Be aware that some students may need to work with earplugs or in areas of the room where they are not distracted by movement.

Focus on meaning, not memorization.

Examples

1. In teaching new words, help students associate the new word to a related word they already understand: "Enmity is from the same base word as enemy."
2. In teaching about remainders, have students group 12 objects into sets of 2, 3, 4, 5, 6, and ask them to count the "leftovers" in each case.
3. Encourage students to generate their own answers and examples as well as ask their own questions.

Use multiple examples, cases, and stories to teach.

Examples

1. Give both abstract and concrete examples of new concepts, such as adding with concrete objects and adding with numbers and formulas.
2. Have students create stories and cases that show applications of concepts they are learning.

Remember the power of practice.

Examples

1. Interleave practice—mix up types of problems, physical skills, or related concepts.
2. Distribute practice—repeat and review with at least two weeks in between.
3. Make practice deliberate—monitor performance in relation to a high standard and focus on needed improvements. Don't keep practice what you already do well.

Source: For more information on applying learning principles, see <http://www.apa.org/ed/schools/cpse/top-twenty-principles.pdf> and <http://ies.ed.gov/ncee/wwc/PracticeGuide.aspx?sid=1>

DOMAIN-SPECIFIC STRATEGIES. As we saw earlier, some procedural knowledge, such as monitoring the traffic while you drive, is not automatic because conditions are constantly changing. Once you decide to change lanes, the maneuver may be fairly automatic, but the decision to change lanes was conscious, based on the traffic conditions around you. **Domain-specific strategies** are consciously applied skills that organize thoughts and actions to reach a goal. To support this kind of learning, teachers need to provide opportunities for practice in many different situations—for example, practice reading with package labels, magazines, books, letters, operating manuals, Web pages and so on. In the next chapter's discussion of problem-solving and study strategies, we will examine other ways to help students develop domain-specific strategies. For now, let's summarize these ideas for developing declarative and procedural knowledge in the *Guidelines: Helping Students Understand and Remember*. We will spend quite a bit of time in the next chapter on developing self-regulatory knowledge.

Domain-specific strategies
Consciously applied skills to reach goals in a particular subject or problem.

MyLab Education Self-Check 8.4

▼ SUMMARY

Elements of the Cognitive Perspective (pp. 328–330)

What is the brain's role in cognition? The human brain is made up of many different modules with specialized functions. All these modules work together to make sense of your ongoing experiences and to learn. Throughout life, every time you learn, you change your brain. For example, individuals who regularly complete tasks such as taxi driving develop certain regions of the brain more than others who do not engage in such activities. Because of the continuing development of the brain, particularly as the prefrontal cortex matures, children begin to engage in complex tasks such as integrating past and present experiences by approximately age 7 or 8.

How does knowledge affect learning? The cognitive approach suggests that one of the most important elements in the learning process is knowledge the individual brings to the learning situation. What we already know determines to a great extent what we will pay attention to, perceive, learn, remember, and forget. Knowledge is categorized as domain-specific (tied to a particular subject) or general and also as declarative, procedural, or self-regulatory. Declarative knowledge is knowledge that can be declared, usually in words or other symbols. Declarative knowledge is “knowing that” something is the case. Procedural knowledge is “knowing how” to do something; it must be demonstrated. Self-regulatory knowledge is “knowing when and why” to apply your declarative and procedural knowledge.

Cognitive Views of Memory (pp. 330–344)

Describe the path from sensory input to recognizing objects. The capacity of sensory memory is great but the duration that this input stays in sensory memory is short—about 3 seconds. In this brief time, the first phase in the process of recognizing objects is feature analysis, or bottom-up processing, because the stimulus must be analyzed into features or components and assembled into a meaningful pattern. The Gestalt principles are one explanation for how features are organized into patterns. In addition to noting features and using these

Gestalt principles, to recognize patterns rapidly, we use what we already know about the situation, information from the context, and our knowledge of prototypes or best examples.

What role does attention play? What we pay attention to is guided to a certain extent by what we already know and what we need to know, so attention is involved in and influenced by all three memory processes shown in Figure 8.1. What takes more attention in the beginning can become more automatic with practice. Some people believe that they can divide their attention, between texting and driving for example, but research shows that very few people are good multitaskers. Some students have attention problems, but teachers must work at gaining and holding everyone's attention for learning.

What is working memory? Working memory is both short-term storage in the phonological loop and visuospatial sketchpad and processing in the episodic buffer, guided by the central executive—it is the workbench of conscious thought. To keep information activated in working memory for longer than about 20 seconds, people use maintenance rehearsal (mentally repeating) and elaborative rehearsal (making connections with knowledge from long-term memory). Elaborative rehearsal also helps move new information to long-term memory. The limited capacity of working memory can also be somewhat circumvented by the control process of chunking. There are individual differences in working memory, and working memory span is related to performance on tasks that require higher-level thinking and controlled attention such as IQ tests and the SAT. Recently, some psychologists have suggested that working and long-term memory are not two separate memory stores. Rather, working memory is the part of long-term memory that works on (processes) currently activated information.

What is cognitive load, and how does it impact information processing? *Cognitive load* refers to the volume of cognitive resources, including perception, attention and memory,

necessary to perform a task. These resources must be devoted not only to organizing and understanding the task, but also to analyzing the solution and ignoring irrelevant stimuli. If cognitive load is high, it can decrease or even inhibit one's ability to perform a task. The goal of good instructional design and good teaching is to *manage* intrinsic load (keep it just right for the students' abilities—in their zone of proximal development) and *reduce* extraneous load (clear away as much as possible).

Long-Term Memory (pp. 344–351)

Compare explicit and implicit memories. The capacity of long-term memory is huge and information can remain in long-term memory indefinitely. The trick is finding it when needed. Memories may be explicit (semantic/declarative or episodic) or implicit (procedural, classical conditioning, or priming).

How is information represented in explicit long-term memory, and what role do schemas play? In explicit (semantic) long-term memory, bits of information may be stored and interrelated in terms of propositional networks, images, concepts, and schemas. The dual coding theory suggests that information coded both verbally and visually (using images) is easier to remember. Much information is stored as concepts. A concept is a mental representation for a category of similar events, ideas, objects, or people that enables people to identify and recognize the members of a group such as books, students, or cats. Concepts provide a manner of organizing diversity among members of a group. Concepts are often represented by prototypes (an ideal example) and exemplars (a representative memory). Concepts also probably are theory-based, that is, based on our ideas about the world and how it works. To organize propositions, images, and concepts, we have schemas, which are data structures that allow us to represent large amounts of complex information, make inferences, and understand new information. In explicit episodic memory, information is stored as events, particularly events in your own life, and may include vivid flashbulb memories.

What is implicit memory? Implicit memories are out-of-awareness memories that still can affect thinking and behavior. There are three kinds of implicit memories: *classical conditioning*, *procedural memory*, and *priming effects*. We discussed classical conditioning of automatic physiological and emotional responses in Chapter 7. Procedural memory includes skills, habits, and scripts—how to perform tasks—in other words, memory for procedural knowledge. Priming is activating information that already is in long-term memory through some out-of-awareness process. Priming may be the fundamental process for retrieval as associations are activated and spread through the memory system.

Why do we forget? Information lost from working memory truly disappears, but information in long-term memory may be available, given the right cues. Information appears to be lost from long-term memory through time decay (neural connections, like muscles, grow weak without use) and interference

(newer memories may obscure older memories, and older memories may interfere with memory for new material).

Teaching for Deep, Long-Lasting Knowledge: Basic Principles and Applications (pp. 352–361)

What supports the development of declarative knowledge?

The way you learn information in the first place affects its recall later. One important requirement is to integrate new material with knowledge already stored in long-term memory using elaboration, organization, imagery, context, desirable difficulty, and effective practice (spaced learning and interleaved practice). The dual coding theory suggests that information coded both verbally and visually is easier to remember. Pictures and words help students learn as long as they are well organized and do not overload working memory. Another view of memory is the levels of processing theory, in which recall of information is determined by how completely it is processed.

Describe three ways to develop declarative knowledge.

Declarative knowledge develops as we integrate new information with our existing understanding. Making the information to be remembered meaningful is important and often is the greatest challenge for teachers. Second, mnemonics are memorization aids including approaches such as the loci method, acronyms, chain mnemonics, and the keyword method. A powerful but limiting way to remember is rote memorization, which can best be supported by part learning and distributed practice. In sum, there are at least two clear lessons for teachers and teaching in the research on learning declarative knowledge. The first is the importance of connections—connecting to what the student already knows, connecting pictures and words to support understanding, connecting different specific examples of concepts to understand the abstract idea, and connecting to the context where information was first learned. The second lesson is the power of deep processing—processing by elaborating new information, processing by forming images, processing by reviewing over time, processing by dealing with difficulty and persisting, and processing through questioning.

Describe some methods for developing procedural knowledge.

Automated basic skills and domain-specific strategies—two types of procedural knowledge—are learned in different ways. There are three stages in the development of an automated skill: cognitive (following steps or directions guided by declarative knowledge), associative (combining individual steps into larger units), and autonomous (where the whole procedure can be accomplished without much attention). Prerequisite knowledge and practice with feedback help students move through these stages. Domain-specific strategies are consciously applied skills of organizing thoughts and actions to reach a goal. To support this kind of learning, teachers need to provide opportunities for practice and application in many different situations.

▼ CONNECT AND EXTEND TO LICENSURE

MULTIPLE-CHOICE QUESTIONS

1. Aanika had been trying hard to memorize the lyrics of a song for a competition. For 2 months, she practiced the song at least 10 times a day. On the day of the competition, Aanika was confident she could sing naturally, as recollecting the lyrics did not require her attention and concentration anymore. This process is known as which one of the following?
 - A. Automaticity
 - B. Episodic Memory
 - C. Priming
 - D. Flashbulb memory
2. Which of the following does NOT help establish deep, long-lasting knowledge?
 - A. Adding meaning to new information by connecting with already existing knowledge.
 - B. Putting small bits of information into larger, more meaningful chunks.
 - C. Using relevant imagery with information, wherever applicable, to aid learning.
 - D. Isolating information from the context to effectively manage working memory and cognitive load.
3. Sometimes memorization work is inevitable, but students do not usually like it. Which of the following strategies is NOT recommended by research for improving performance in memorization-heavy tasks?
 - A. Encourage students to perform massed practice (i.e., practice for a single, long period) and avoid distributed practice (i.e., splitting learning into smaller periods with resting intervals).
 - B. Do frequent reviews of important information every several weeks, and update these reviews with more recent information.
 - C. Re-expose students to important information in assignments, even several weeks after they first learned the material.

- D. Give tests and exams that are cumulative to encourage students to review materials and space out their study sessions on their own.
4. Which one of the following examples would be least relevant to the use of implicit memory?
 - A. John, a school basketball representative, is demonstrating how to perform basic basketball moves to newcomers.
 - B. Mary, a dentist, is demonstrating how to correctly clean braces to her clients.
 - C. Lee, a teacher, is trying to teach middle-school science class for the first time.
 - D. Samara, a chef, is cooking her signature dish for one of her regular customers.

CONSTRUCTED-RESPONSE QUESTIONS

Case

History is one of the most content-heavy subjects in secondary school. In the previous exam, students in Michelle's class did not do well. More than half of the students scored 60% and below. When she requested students' feedback on her classes to identify potential reasons for their poor performance, she discovered most students found history to be boring and all about memorization. In addition, they claimed it was frustrating as they found most content to be similar and indistinguishable. To improve her students' learning outcomes, Michelle set out to restructure her class.

5. Identify and elaborate on the specific type of knowledge that is most relevant to the discipline of history.
6. Think of some strategies that Michelle could potentially adopt to improve her lesson plan and her students' learning outcomes.

MyLab Education **Licensure Exam**

▼ WHAT WOULD THEY DO?

TEACHERS' CASEBOOK: Remembering the Basics

Here is how a number of expert teachers responded to the situation at the beginning of the chapter about students who often have trouble remembering key information from one day or week to the next.

PAULA COLEMERE • Special Education Teacher • English, History

McClintock High School, Tempe, AZ

I always evaluate my test results to see if student mistakes came from a poorly written question. If a number of students are missing the same test question, I review the answers to see what went wrong. This helps me to see if I need to alter my test or alter my instruction. As a teacher, I am constantly reflecting on my successes and defeats. Did I set a purpose for learning at the beginning of the unit? Did I make connections to prior knowledge?

Before giving this unit test, was there sufficient formative assessment along the way? It makes more sense to pay attention during lessons to see what students understand and where they need more instruction. For students who are struggling along the way, I would spend a little more time on a concept and offer extra help during lunch or after school to help them gain a better understanding. I would teach them how to organize information and how to study. Chunking information is another good strategy to help students who struggle. I also teach test-taking skills to help students build confidence in their test-taking abilities.

LAUREN ROLLINS • First Grade Teacher

Boulevard Elementary School, Shaker Heights, OH

I promote different styles of teaching and learning in my classroom. However, I usually present some material, such as vocabulary

words, math facts, and sight words, using a rote memory approach. In this situation, that method seemed to work well for the majority of the students, but not all of them. Therefore, it is my job as the teacher to create opportunities for those students to work with the material in a different way. In the example of the vocabulary, I would help the students create their own dictionaries where they would define each vocabulary word in a way that makes sense to them and provide examples that they would remember. Once the vocabulary becomes more meaningful to them, it will be easier for them to remember. In my classroom, I try to provide the students with a variety of methods to practice these types of concepts. Coloring pages, matching activities, word/number searches, secret codes, games, books, and so on are available to my students to help them practice sight words and math facts every day. I encourage my students to serve as peer tutors and enlist parents to work one on one with students as well. Every little bit helps!

SARA VINCENT • Special Education Teacher

Langley High School, McLean, VA

Every individual learns differently. The teacher in this scenario should first take time to identify how the students learn material effectively. Their inability to master the material may stem from a note-taking problem; students may benefit more from a cloze note-taking format rather than attempting to decipher what information is important. In addition, the teacher should administer smaller assessments more frequently before the final test in order to determine if all students are grasping the information. The teacher could then provide remediation to those students who are still struggling with the material. Every day, a teacher should evaluate her delivery of the information. She should also assess if the students are learning the material. In other words, no one can be a perfect teacher; effective teaching is always a work in progress.

JESSICA N. MAHTABAN • Eighth-Grade Math

Woodrow Wilson Middle School, Clifton, NJ

Mind mapping would be a great tool to help students retain and retrieve information. It is a fast and fun way to take visual notes, expand students' visual thinking skills, and make learning meaningful. Graphic organizers are another phenomenal instrument to use that steers the students away from just memorizing facts. A graphic organizer expands students' higher-level thinking skills and helps them make connections. A student's prior knowledge helps him or her build on lessons and make connections with new information. When a student can relate to the content and have meaningful connections, a whole new classroom emerges!

The next step would be to teach students how to comprehend the material rather than just retain the material. Teachers need to provide students with strategies they can use to comprehend all the subjects. Also, teachers need to provide students with plenty of modeling! Modeling all the strategies students can use to comprehend material will benefit the students the most!

JENNIFER L. MATZ • Sixth Grade Teacher

Williams Valley Elementary, Tower City, PA

I review vocabulary every day at the start of the lesson. This only takes a few minutes. My students make flip books. Flip books are better than flash cards because students can test themselves and flash cards can be lost. We write the definition, but then we write it in "kid" words too. I ask them to explain words or events in their own words.

Some review ideas are: Make up two sets of cards: one set with the words, the other set with the definition. Pass out both

sets to the class, and ask "word people" to find their "matching definition." Another is to have a student come to the front and cover his eyes. Write the word on the board, and have the class give him clues. They may not say the word—he must guess it.

Make up songs to help students remember information. When I taught second grade, we had an array of grammar songs and rhymes to remember nouns, pronouns, and so on. My students made up movements. You can pair students who have mastered material with those who have not. Students often have better ways of remembering things than we can teach them.

KELLY L. HOY • Fifth-Grade Humanities Teacher

Katherine Delmar Burke School, San Francisco, California

As a teacher I find it challenging, yet extremely rewarding, to help students who are figuring out how they learn. Each student is a unique puzzle and it's important to create a safe space where students feel comfortable taking risks, trying new techniques, and communicating their successes and failures. In my fifth-grade classroom I tout, "It's not about the grade; it's about the learning." I would impress upon the children that we are a family of learners and elicit the strategies or techniques that lead them to master the material. This idea of sharing how we study or learn could be done directly after a test, at the start of a unit, or in preparation for an upcoming unit test.

My first inclination in helping the students who are struggling to memorize the foundational vocabulary would be to carve out time to meet with each student. Having conversations with the children is invaluable on a myriad of levels. I would be curious to know how much time they put into studying the material. How do they study or what approach are they using to learn the information? What has been successful for them in their past learning experiences? With technology so readily available to students, I would want to know if they are becoming distracted from the task at hand. (I certainly am guilty of the distraction of social media.) Not retaining the material could also be a matter of discipline, and maybe the students need someone to oversee the work. I might suggest the students time themselves and take intermittent breaks during study time. This one-on-one conversation would hopefully lead to a discussion about how the students think they learn best.

After conferring with the students and probing to find out how they approach learning, I would give them some options that deviate from a rote memory approach. Looking up the derivation of the vocabulary and where it comes from can sometimes help the student categorize the word and shows it in relationship to other words. Another way to commit the word to memory would be to create a graphic organizer in which the student folds a paper in quadrants with the vocabulary word in the center. In each quadrant the student: writes synonyms, draws a picture to represent the word, creates a child friendly definition and writes all the things "the word is not." The children might need to hear the word, so they could record themselves saying the word and playing around with its meaning. Engaging in a game of charades, or drawing the definition and having people guess the word could be another playful way to learn its meaning. Children can create a comic book or create graphics that use the vocabulary in a meaningful way. Another way to learn pertinent vocabulary would be to use technology and create a "podcast" or a "tweet" using the vocabulary. With the teacher's guidance, the students are creating interactive ways to engage with vocabulary and use a variety of strategies to master the basics.

chapter nine

COMPLEX COGNITIVE PROCESSES

TEACHERS' CASEBOOK: Uncritical Thinking

This year's class is worse than any you've ever had. You assigned a research paper, and you find more and more students are using the Web for all their information. In itself, using the Web is not bad, but the students appear to be completely uncritical about what they find on the Internet. "If it is on the Web, it must be right" is the attitude of most students. Their first drafts are filled with quotes that seem very biased to you, but there are no sources cited or listed. It is not just that students don't know how to reference their work. You are more concerned that they cannot critically evaluate what they are reading. And all they are reading is the Net!

CRITICAL THINKING

- How would you help your students evaluate the information they are finding on the Web?
- Beyond this immediate issue, how will you help students think more critically about the subjects you are teaching?
- How will you take into account the cultural beliefs and values of your students as you support their critical thinking?

WHAT WOULD YOU DO?

Gudiny/Shutterstock

OVERVIEW AND OBJECTIVES

In the previous chapter we focused on the development of knowledge—how people make sense of and remember information and ideas. In this chapter, we consider complex cognitive processes that lead to understanding. Understanding is more than memorizing. It is more than retelling in your own words. Understanding involves appropriately transforming and using knowledge, skills, and ideas. These understandings are considered “higher-level cognitive objectives” in a commonly used system of educational objectives (L. W. Anderson & Krathwohl, 2001; B. S. Bloom, Engelhart, Frost, Hill, & Krathwohl, 1956). We will focus on the implications of cognitive theories for the day-to-day practice of teaching.

Because the cognitive perspective is a philosophical orientation and not a unified theoretical model, teaching methods derived from it are varied. In this chapter, we will first examine the complex cognitive process of metacognition—using knowledge and skills about learning, motivation, and yourself to plan and regulate your own learning. Next we explore four important areas in which cognitive theorists have made suggestions for learning and teaching: learning strategies, problem solving, and critical thinking, including argumentation. Then we will consider the question of how to encourage the transfer of learning from one situation to another to make learning more useful. Finally, we bring together many key ideas from this chapter by considering how teaching can develop robust knowledge and complex learning.

By the time you have completed this chapter, you should be able to:

- Objective 9.1 Discuss the roles of metacognition in learning and remembering.
- Objective 9.2 Describe several learning and study strategies that help students develop their metacognitive abilities.
- Objective 9.3 Explain the processes involved in problem solving and the factors that can interfere with successful problem solving.
- Objective 9.4 Identify factors that influence students’ abilities to think critically and to form and support arguments.
- Objective 9.5 Discuss how, why, and when knowledge learned in one situation might be applied to new situations and problems.
- Objective 9.6 Explain what characterizes robust knowledge, how to recognize it, and how teaching can develop robust knowledge.

Teachers' Casebook—Uncritical Thinking: What Would They Do?

Executive control

processes Processes such as selective attention, rehearsal, elaboration, and organization that influence encoding, storage, and retrieval of information in memory.

Metacognition Knowledge about our own thinking processes.

metacognition is involved in the “reflection, brooding about what it is that you know.” Cordula Artelt and Wolfgang Schneider (2015) describe metacognition as consisting of knowledge and skills—*knowledge* about our own information-processing capabilities, the cognitive tasks you face, and the strategies needed to cope with those tasks, as well as the *skills* involved in applying those strategies. So metacognition is higher-order knowledge about your own thinking as well as your ability to use this knowledge to manage your own cognitive processes—such as comprehension or problem solving (Barzilai & Zohar, 2014).

The complex cognitive skills we will examine in this chapter take us beyond the simpler, more basic processes of perceiving, representing, and remembering (though after reading Chapter 8 you may believe that there is nothing “simple” about these). Much of what we consider in this chapter has been described as “higher-order” thinking, that is, thinking that moves beyond remembering or repeating facts and ideas to truly understanding, dissecting, and evaluating those facts or even creating new concepts and ideas of your own. Jerome Bruner (1973) once wrote a book about this kind of thinking entitled *Beyond the Information Given*—a good way to describe higher-level thinking. As Bruner (1996) later noted:

Being able to “go beyond the information” given to “figure things out” is one of the few untarnishable joys of life. One of the great triumphs of learning (and of teaching) is to get things organized in your head in a way that permits you to know more than you “ought” to. And this takes reflection, brooding about what it is that you know. (p. 129)

In Chapter 14 we will use Bloom’s taxonomy to categorize levels of thinking in a hierarchy from the *lower levels* of remembering, understanding, and applying, to the *higher levels* of analyzing, evaluating, and creating. Of course, it is difficult to know exactly what kind of thinking any particular student is doing without also knowing the basis for that thinking. A student who parrots a principle of balance memorized from a textbook might sound “higher level,” but the thinking is just lower-level rote memory. I am reminded of the great bar scene in the film *Good Will Hunting* when the pretentious graduate student tried to embarrass Matt Damon’s friend with an impressive analysis of history, only to be devastated when Damon nailed him for basing his supposed creative analysis entirely on passages from textbooks—great stuff! In this chapter we will explore what it takes for students to engage in truly deep, complex thinking.

METACOGNITION

In Chapter 8 we discussed a number of **executive control processes**, including attention, rehearsal, organization, imagery, elaboration, and practice. These executive control processes are sometimes called *metacognitive* skills, because they can be intentionally used to regulate cognition.

Metacognitive Knowledge and Regulation

Metacognition literally means cognition about cognition, or thinking about thinking. In the Bruner quote earlier,

There are many examples of metacognitive knowledge and skills, including knowing when to skim and when to read carefully, knowing what time of day you are most productive, deciding where to focus attention, determining if you understood what you just read, devising and revising a plan, using strategies such as mnemonics, determining if you have studied enough to pass a test, deciding to get help, and generally orchestrating your cognitive powers to reach a goal (Castel et al., 2011; Meadows, 2006). In second-language learning, you have to focus on the important elements of the new language, ignore distracting information, and suppress what you know in the first language that interferes with or confuses learning the second language (Engel de Abreu & Gathercole, 2012).

Metacognition involves all three kinds of knowledge we discussed earlier: (1) *declarative knowledge* about yourself as a learner, the factors that influence your learning and memory, and the skills, strategies, and resources needed to perform a task—*knowing what* to do; (2) *procedural knowledge* or *knowing how* to use the strategies; and (3) *self-regulatory knowledge* to ensure the completion of the task—*knowing the conditions*, when and why, to apply the procedures and strategies (Bruning et al., 2011). Metacognition is the strategic application of this declarative, procedural, and self-regulatory knowledge to accomplish goals and solve problems (Schunk, 2016). Metacognition also includes appreciating the value of applying cognitive strategies in learning (Pressley & Harris, 2006).

There are three essential metacognitive skills: *planning*, *monitoring*, and *evaluating* (A. Brown, 1987; T. O. Nelson, 1996). *Planning* involves deciding how much time to give to a task, which strategies to use, how and where to start, which resources to gather, what order to follow, and so on. *Monitoring* is the real-time awareness of “how I’m doing.” Monitoring is asking, “Is this making sense? Am I trying to go too fast? Should I be taking notes?” *Evaluating* involves making judgments about the processes and outcomes of thinking and learning. “Should I get help? Give up for now? Is this paper (painting, model, poem, plan, etc.) finished?” The notion of *reflection* in teaching—thinking back on what happened in class and why, and thinking forward to what you might do next time—is really about metacognition in teaching (Barzilai & Zohar, 2014; Sawyer, 2006).

Of course, we don’t have to be metacognitive all the time. Some actions become routine or habits. Metacognition is most useful when tasks are challenging, but not too difficult. And even when we are planning, monitoring, and evaluating, these processes are not necessarily conscious, especially in adults. We may use them automatically without being aware of our efforts (Perner, 2000). Experts in a particular field plan, monitor, and evaluate as second nature; they have difficulty describing their metacognitive knowledge and skills (Pressley & Harris, 2006; Reder, 1996).

Individual Differences in Metacognition

People differ in how well and how easily they use metacognitive strategies. Some differences in metacognitive abilities are the result of development. Younger children, for example, may not be aware of the purpose of a lesson—they may think the point is simply to finish. They also may not be good at gauging the difficulty of a task—they may think that reading for fun and reading a science book are the same (Gredler, 2009b). As children grow older, they are more able to exercise executive control over strategies. For example, they are more able to determine if they have understood instructions or if they have studied enough to remember a set of items. Metacognitive abilities begin to develop around ages 5 to 7 and improve throughout school (Flavell, Green, & Flavell, 1995; Woolfolk & Perry, 2015). But as we will see many times in this book, *knowing and doing are not the same*. Students may know that it is better to study on a regular basis but still cram in the hopes that “cramming will work this time.”

Not all differences in metacognitive abilities have to do with age or maturation (Lockl & Schneider, 2007; Vidal-Abarca, Mañá, & Gil, 2010). Some individual differences in metacognitive abilities are probably caused by differences in biology or learning experiences. Many students diagnosed as having learning disabilities have problems monitoring their attention (Hallahan, Kauffman, & Pullen, 2015), particularly with long tasks.

MyLab Education
Video Example 9.1

In this video, a young boy shows his metacognitive awareness as he talks about and shows his skills at remembering. What metacognitive skills does he show, and how might a teacher help to foster them?

Working to improve metacognitive skills can be especially important for students who often have trouble in school (Schunk, 2016; H. L. Swanson, 1990).

Lessons for Teachers: Developing Metacognition

Like any knowledge or skill, metacognitive knowledge and skills can be learned and improved, as you will see next.

METACOGNITIVE DEVELOPMENT FOR YOUNGER STUDENTS. In his second-grade classroom in Queens, New York, Daric Desautel (2009) worked with mostly Latino/a and Asian students. As part of teaching literacy, Desautel decided to focus on student metacognitive knowledge and skills such as setting goals, planning, evaluating achievements, and self-reflection to help students develop the habit of “looking in” at their own thinking. He also included self-reflections to help students evaluate their writing and gain insight into themselves as readers and writers. For example, one self-reflection included a checklist asking:

- Did you pick a topic that you know all about?
- Did you write a special beginning that makes the reader want more?
- Did you organize your thoughts and make a Table of Contents?
- Did you pick the right kind of paper and illustrate your book clearly?
- Did you reread your work to check for SOUND, SENSE, ORDER, and GOOFS?

Desautel was successful in helping all his students, not just the most verbal and advanced, develop metacognitive knowledge. One student noted in his reflection, “I worked hard and did my best to make this book. I like nonfiction books better than stories. Next time, I would write about a different sport” (p. 2011).

In her work with first- and second-graders, Nancy Perry found that asking students two questions helped them become more metacognitive. The questions were “What did you learn about yourself as a reader/writer today?” and “What did you learn that you can do again and again and again?” When teachers asked these questions regularly during class, even young students demonstrated fairly sophisticated levels of metacognitive understanding and action (Perry et al., 2000).

Many of the cooperating teachers I work with use a strategy called **KWL** to guide nonfiction reading and inquiry in general. This general frame can be used with most grade levels. The steps are:

- K** What do I already *know* about this subject?
- W** What do I *want* to know?
- L** At the end of the reading or inquiry, what did I *learn*?

The KWL frame encourages students to “look within” and identify what they bring to each learning situation, where they want to go, and what they actually achieved—a very metacognitive approach to learning. Look at Figure 9.1 and let’s consider the example of learning about “crocodiles” (Gillet, Temple, Temple, & Crawford, 2017). In the **K** step, the teacher guides the class in brainstorming—what do you already know (or think you know) about crocodiles? Next, in the **W** step, what are you curious about? What do you want to learn? What interests you? The students write down specific questions to answer so they have a personal commitment to the information. Next, considering what you know and want to learn, what kinds of information do you expect to find when you read? How might the author have organized the material—using what categories or major divisions (Vacca, Vacca, & Mraz, 2014)? These “Categories of Information I Expect to Use” go on the strategy sheet as you can see in Figure 9.1. Finally, after reading, students complete the **L** step by writing down what they learned (retrieval practice), then checking to see if they have answered their questions. Student should share answers and perhaps debate any disagreements. Some teachers encourage their students to use the KWL strategy to organize taking notes as they read. Some teachers include an additional stage after the **W** step—**H**—how do I find out what I want to know? Figure 9.2 on page 372 is an example of a KWHL strategy sheet for a health class.

KWL A strategy to guide reading and inquiry: Before—What do I already know? What do I want to know? After—What have I learned?

FIGURE 9.1

METACOGNITIVE DEVELOPMENT FOR SECONDARY AND COLLEGE STUDENTS

(LIKE YOU). For older students, teachers can incorporate metacognitive questions into their lessons, lectures, and assignments. For example, David Jonassen (2011, p. 165) suggests that instructional designers incorporate these questions into hypermedia learning environments to help students become more self-reflective:

- What are my intellectual strengths and weaknesses?
- How can I motivate myself to learn when I need to?
- How good am I at judging how well I understand something?
- How can I focus on the meaning and significance of new information?
- How can I set specific goals before I begin a task?
- What questions should I ask about the material before I begin?
- How well have I accomplished my goals once I'm finished?
- Have I learned as much as I could have once I finish a task?
- Have I considered all options after I solve a problem?

Metacognition includes knowledge about using many strategies in learning—our next topic.

Connect and Extend to PRAXIS II®

Learning Strategies (I, A1)

For suggestions about their effective use, take a look at the study skills site developed by the Virginia Polytechnic Institute (ucc.vt.edu), and search for study skills. In fact, most colleges and universities have a section on study skills on their Websites. Also see studygs.net for more ideas.

LEARNING STRATEGIES

Most teachers will tell you that they want their students to “learn how to learn.” Years of research indicate that using good learning strategies helps students learn and that these strategies can be taught (Hamman, Berthelot, Saia, & Crowley, 2000; Pressley & Harris, 2006). But were you taught “how to learn”? Powerful and sophisticated learning strategies and study skills are seldom taught directly until high school or even college, so most students have little practice with them. In contrast, early on, students usually discover repetition and rote learning on their own, so they have extensive practice with these strategies. And, unfortunately, some teachers think that memorizing is learning (Beghetto, 2008; Woolfolk Hoy & Murphy, 2001). This may explain why many students cling to flash cards and memorizing—they don’t know what else to do (Willoughby, Porter, Belsito, & Yearsley, 1999).

As you saw in Chapter 8, the way we first learn something greatly influences how readily we remember the information and how appropriately we can apply the knowledge later. First, students must be *cognitively engaged* in order to learn; they have to *focus attention* on the relevant or important aspects of the material. Second, they have to *invest effort*, make connections, elaborate, translate, invent, organize, reorganize, and practice retrieving to think and *process deeply*—the greater the practice and processing, the stronger the learning. Finally, students must *regulate and monitor* their own learning—keep track of what is making sense and notice when a new approach is needed; they must be *metacognitive*. The emphasis today is on helping students develop effective learning strategies that focus attention and effort, process information deeply, and monitor understanding (Brown et al., 2014).

Being Strategic About Learning

Learning strategies are a special kind of procedural knowledge—*knowing how* to do something. There are thousands of strategies. Some are general and taught in school, such as summarizing or outlining. Others are specific to a subject, such as using a mnemonic to remember the order of the planets: “My Very Educated Mother Just Served Us Nachos” for Mercury, Venus, Earth, Mars, Jupiter, Saturn, Uranus, and Neptune. Other strategies may be unique, invented by an individual to learn Chinese characters, for example. Learning strategies can be cognitive (summarizing, identifying the main idea), metacognitive (monitoring comprehension—do I understand?), or behavioral (setting a timer to work until time’s up) (Cantrell, Almasi, Carter, Rintamaa, & Madden, 2010). All are ways of accomplishing a learning task that are intentionally applied when usual

Learning strategies A special kind of procedural knowledge—*knowing how* to approach learning tasks.

methods have not worked and strategic effort is needed (K. R. Harris, Alexander, & Graham, 2008). Over time, as you become more expert at using the strategies, you need less intentional effort. Ultimately you may become more automatic in applying the strategies; in other words, the strategies will become your usual way of accomplishing that kind of task—until they don't work and you need new strategies.

Skilled learners have a wide range of learning strategies that they can apply fairly automatically. Using learning strategies and study skills is related to higher grade-point averages (GPAs) in high school and persistence in college (Robbins et al., 2004). Researchers have identified several important principles:

1. Students must be exposed to a number of different strategies, not only general learning strategies but also very specific strategies for particular subjects, such as the graphic strategies described later in this section.
2. Students should be taught self-regulatory (conditional) knowledge about *when*, *where*, and *why* to use various strategies. Although this may seem obvious, teachers often neglect this step. A strategy is more likely to be maintained and employed if students know when, where, and why to use it.
3. Students may know when and how to use a strategy, but unless they also develop the desire to employ these skills, general learning ability will not improve. Remember, left to their own, many students, adult students included, fall back on comfortable but ineffective strategies, even if they know how to do the more effective strategy (Son & Simon, 2012). Several learning strategy programs include a motivational training component.
4. Students need to believe that they can learn new strategies, that the effort will pay off, and that they can “get smarter” by applying these strategies.
5. Students need background knowledge and useful schemas in the area being studied to make sense of learning materials. It will be difficult to find the main idea in a paragraph about *ichthyology*, for example, if you don't know much about fish. So students may need direct instruction in key content knowledge along with strategy training. Table 9.1 summarizes several learning strategies.

TABLE 9.1 • Examples of Learning Strategies

	EXAMPLES
Planning and Focusing Attention	Setting goals and timetables Underlining and highlighting Skimming, looking for headings and topic sentences
Organizing and Remembering	Making organizational charts Creating flowcharts, Venn diagrams Using mnemonics, imagery Using analogies to build structures for knowledge (Is what you are learning like a tree? a town? a map?)
Comprehension	Creating concept maps, webs Summarizing, outlining, and note taking Creating examples Explaining to a peer
Cognitive Monitoring	Making predictions Identifying what doesn't make sense
Practice	Using part practice Using whole practice Using retrieval practice: self-testing and self-questioning

DECIDING WHAT IS IMPORTANT. You can see from the first entry in Table 9.1 that learning begins with focusing attention—deciding what is important. But distinguishing the main idea from less important information is not always easy. Often students focus on the “seductive details” or the concrete examples, perhaps because these are more interesting (Gardner, Brown, Sanders, & Menke, 1992). You may have had the experience of remembering a joke or an intriguing example from a lecture, but not being clear about the larger point the professor was trying to make. Finding the central idea is especially difficult if you lack prior knowledge in an area and if the amount of new information provided is extensive. Teachers can give students practice using signals in texts such as headings, bold words, outlines, or other indicators to identify key concepts and main ideas (Lorch, Lorch, Ritchey, McGovern, & Coleman, 2001).

SUMMARIES. Creating summaries can help students learn, but students have to be taught how to summarize (Byrnes, 1996; Palincsar & Brown, 1984). Jeanne Ormrod (2016) summarizes these suggestions for helping students create summaries. Ask students to:

- Find or create a topic sentence for each paragraph or section.
- Identify big ideas that cover several specific points.
- Find some supporting information for each big idea.
- Delete any redundant information or unnecessary details.

Begin by doing summaries of short, easy, well-organized readings. Introduce longer, less organized, and more difficult passages gradually. Initially it may be useful to provide a scaffold such as: This paragraph is about _____ and _____. They are the same in these ways: _____, but different in these ways: _____. Ask students to compare their summaries and discuss what ideas they thought were important and why—they should be sure to provide evidence.

Two other study strategies that are based on identifying key ideas are underlining texts and taking notes.

STOP & THINK How do you make notes as you read? Look back over the past several pages of this chapter. Are my words highlighted yellow or pink? Are there marks or drawings in the margins, and if so, do the notes pertain to the chapter or are they grocery lists and doodles? •

UNDERLINING AND HIGHLIGHTING. Do you underline or highlight key phrases in textbooks? Underlining and note taking are probably two of the most frequent but ineffectively used strategies among college students. One common problem is that students underline or highlight too much, and students who highlight a lot generally learn less. So think carefully about why you are highlighting a particular passage and justify your choices to yourself. Then when you reread, consider those questions again—why did I highlight this? Why is it important? Asking yourself those questions stimulates two powerful learning processes: deeper processing and retrieval practice (Yue, Strom, Kornell, & Bjork, 2015). In addition to being selective, you also should actively transform the information into your own words as you underline or take notes. Don’t rely on the words of the book. Note connections between what you are reading and other things you already know. Draw diagrams to illustrate relationships. Finally, look for organizational patterns in the material, and use them to guide your underlining or note taking.

TAKING NOTES. Taking good lecture notes is not an easy task. You have to hold the lecture information in working memory; select, organize, and transform the important ideas and themes before the information “falls off” your working memory workbench; and write down the ideas and themes—all while you are still following the lecture. As you fill your notebook with words and try to keep up with a lecturer, you may wonder

if taking notes makes a difference. It does, if the strategy is used well. Let's see what the research says (Armbruster, 2000; Bui, Myerson, & Hale, 2013; Kiewra, 2002; Kobayashi, 2005; Peverly et al., 2007; Peverly, Brobst, Graham, & Shaw, 2003).

- Taking notes focuses attention during class. Of course, if taking notes distracts you from actually listening to and making sense of the lecture, then note taking may not be effective.
- Taking organized notes works well for students with good working memory, but using a laptop to transcribe lectures can be better for students with poor working memories, at least for short lectures.
- Taking organized notes makes you construct meaning from what you are hearing, seeing, or reading, so you elaborate, translate into your own words, retrieve, and remember. Even if students don't review notes before a test, taking them in the first place appears to aid learning, especially for those who lack prior knowledge in an area.
- Notes provide extended external storage that allows you to return and review. Students who use their notes to study tend to perform better on tests, especially if they take many high-quality notes—more is better as long as you are capturing key ideas, concepts, and relationships, not just intriguing details or jokes.
- Expert students match notes to their anticipated use and modify strategies after tests or assignments; use personal codes to flag material that is unfamiliar or difficult; fill in holes by consulting relevant sources (including other students in the class); and record information verbatim only when a verbatim response will be required. In other words, they are *strategic* about taking and using notes.

Even with these advantages, remember the caveat mentioned earlier. It is possible that taking well-organized notes that capture the important ideas in lecture is easier for students with better working memory abilities. When students have more-limited working memories, they might need to focus on understanding the teacher and transcribing as much as possible, as long as they are fast typists. Also, middle school and high school students with learning disabilities who use a strategic note-taking form (see www.ldonline.org and search “note taking” for an example) recall and understand significantly more key ideas from science lectures than students in control groups who used conventional note-taking methods (Boyle, 2010a, 2010b; Boyle & Weishaar, 2001).

Figure 9.3 on the next page is a general form that can be used in many note-taking situations. Dividing up the page is an idea from Cornell notes, devised by Walter Pauk of Cornell University, who wrote the classic guide, *How to Study in College* in the 1950s. It is still available (Pauk & Owens, 2013). This form could be useful for any student who needs extra guidance in note taking.

Visual Tools for Organizing

To use underlining and note taking effectively, you must identify main ideas. In addition, you must understand the organization of the text or lecture—the connections and relationships among ideas. Some visual strategies have been developed to help students with this key organizational element (Van Meter, 2001). **Concept maps** are graphical tools for organizing and representing knowledge and relationships within a particular field or on a given topic (Hagemans, van der Meij, & de Jong, 2013; van der Meij, 2012). Figure 9.4 on page 377 is a concept map of a Web site for creating concept maps from the Institute for Human and Machine Cognition Cmap tools. You may have referred to these interconnected ideas as *webs*.

In a review of 55 studies with students from fourth grade to graduate school and subjects ranging from science to statistics to nursing, John Nesbit and Olusola Adesope (2006) concluded that, “in comparison with activities such as reading text passages, attending lectures, and participating in class discussions, concept mapping activities are more effective for attaining knowledge retention and transfer” (p. 434). Having students

“map” relationships by noting causal connections, comparison/contrast connections, and examples improves recall. One of my doctoral students at Ohio State even used **Cmaps**, the free downloadable tools from the Web site shown in Figure 9.4, to plan his dissertation and organize all the reading for his doctoral examinations. Computer Cmaps can be linked to the Internet, and students in different classrooms and schools all over the world can collaborate on them. Students should compare their filled-in “maps” and explain the differences in their thinking to each other; explanation is another good study strategy that encourages deeper processing and *retrieval practice*—a powerful learning strategy, as you will see soon.

Instructor-provided maps can serve as guides for studying. Mieke Hagemans and her colleagues (2013) found that color-coded concept maps helped high school physics students master complex concepts. The concept maps were part of a computer program. The maps changed color as the students completed study in that section of the map, so students had a scaffold to guide them through the reading and assignments and even

Cmaps Tools for concept mapping developed by the Institute for Human and Machine Cognition that are connected to many knowledge maps and other resources on the Internet.

FIGURE 9.4

remind them, for example, that they had not spent enough time on the assignments on “acceleration” in their study of “velocity.” Finally, concept maps can be an effective form of practice. After reading some text or hearing a lecture, review the key ideas by drawing a concept map to represent the information (Blunt & Karpicke, 2014).

There are other ways to visualize organization, such as Venn diagrams, which show how ideas or concepts overlap, and tree diagrams, which show how ideas branch off each other. Time lines organize information in sequence and are useful in classes such as history or geology (Rau, Aleven, & Rummel, 2015).

Retrieval Practice: Powerful But Underused

As mentioned earlier, one of the most powerful learning strategies is **retrieval practice**, also called the *testing effect* or *active retrieval* (Pashler et al. 2007). You first met this concept in Chapter 8 when we discussed “Teaching for Deep, Long-Lasting Knowledge.” In study after study over decades, researchers found that trying to actively recall key ideas from readings—testing yourself about what you read or heard in lectures—has proved much more effective than rereading the material or many other ways of studying (Dunlosky et al., 2013). To benefit from this powerful strategy, students can practice recalling what they have learned by listing key ideas, drawing concept maps, explaining to a friend, teaching another student, completing a KWL worksheet, taking a self-test, or anything else that requires active retrieval of the knowledge. Frequent tests and quizzes, even ungraded ones, are a form of retrieval practice. Unfortunately, these strategies are seldom used, in part because students don’t enjoy them. One study of college students found (again) that active retrieval was more effective than rereading in learning from a passage about Salvador Dali, but the student still preferred rereading (Clark & Svinicki, 2015).

Retrieval practice/testing effect Practicing by retrieving information from memory instead of rereading or restudying—more effective because retrieval seems to help memories consolidate in the brain and strengthens the neural pathways so the knowledge is easier to find later.

Reading Strategies

As we saw earlier, effective learning strategies should help students *focus attention*, *invest effort* (connect, elaborate, translate, organize, summarize) so they *process information deeply*, *monitor* their understanding, then cement learning through *retrieval practice*. A number of strategies support these processes in reading. Many strategies use mnemonics to help students remember the steps involved. For example, one strategy that can be used for any grade above later elementary is **READS**:

- R** Review headings and subheadings.
- E** Examine boldface words.
- A** Ask, “What do I expect to learn?”
- D** Do it—Read!
- S** Summarize in your own words. (Friend & Bursuck, 2015)

A strategy that can be used in reading literature is **CAPS**:

- C** Who are the characters?
- A** What is the aim of the story?
- P** What problem happens?
- S** How is the problem solved?

These strategies are effective for several reasons. First, following the steps makes students more aware of the organization of a given chapter. How often have you skipped reading headings entirely and thus missed major clues about the way the information was organized? Next, these steps require students to study the chapter in sections instead of trying to learn all the information at once. This makes use of *distributed practice*. Answering questions about the material forces students to process the information more deeply.

No matter what strategies you use, students have to be taught how to use them. *Direct teaching*, *explanation*, *modeling*, and *practice with feedback* are necessary and are especially important for students with learning challenges and students whose first language is not English.

Applying Learning Strategies

One of the most common findings in research on learning strategies involves **production deficiencies**. Students learn strategies, but do not apply them when they could or should (Schunk, 2016; Son & Simon, 2012). This is especially a problem for students with learning disabilities. For these students, executive control processes (metacognitive strategies) such as planning, organizing, monitoring progress, and making adaptations often are underdeveloped (Kirk, Gallagher, Anastasiow, & Coleman, 2006). It makes sense to teach these strategies directly. To ensure that students actually use the strategies they learn, several conditions must be met.

APPROPRIATE TASKS. First, of course, the learning task must be *appropriate*. Why would students use more complex learning strategies when the task set by the teacher is to “learn and return” the exact words of the text or lecture? With these tasks, teachers reward memorizing, and the best strategies involve distributed practice and perhaps mnemonics (described in Chapter 8). But hopefully, contemporary teachers use few of these kinds of tasks, so if the task is *understanding*, not memorizing, what else is necessary?

VALUING LEARNING. The second condition for using sophisticated strategies is that students must *care* about learning and understanding and believe learning strategies will help them reach those goals (Zimmerman & Schunk, 2001). I was reminded of this in my educational psychology class one semester when I enthusiastically shared an article about study skills from the newspaper *USA Today*. The gist of the article was that students should continually revise and rewrite their notes from a course, so that by the end, all their understanding could be captured in one or two pages. Of course, the majority

READS A five-step reading strategy: Review headings; Examine boldface words; Ask, “What do I expect to learn?”; Do it—Read; Summarize in your own words.

CAPS A strategy that can be used in reading literature: Characters, Aim of story, Problem, Solution.

Production deficiency Students learn problem-solving strategies, but do not apply them when they could or should.

TABLE 9.2 • Teaching Strategies for Improving Students' Metacognitive Knowledge and Skills

These eight guidelines taken from Pressley and Woloshyn (1995) should help you in teaching any metacognitive strategy.

- Teach a few strategies at a time, intensively and extensively as part of the ongoing curriculum.
- Model and explain new strategies.
- If parts of the strategy were not understood, model again and re-explain strategies in ways that are sensitive to those confusing or misunderstood aspects of strategy use.
- Explain to students where and when to use the strategy.
- Provide plenty of practice, using strategies for as many appropriate tasks as possible.
- Encourage students to monitor how they are doing when they are using strategies.
- Increase students' motivation to use strategies by heightening their awareness that they are acquiring valuable skills—skills that are at the heart of competent functioning.
- Emphasize reflective processing rather than speedy processing; do everything possible to eliminate high anxiety in students; encourage students to shield themselves from distractions so they can attend to academic tasks.

Source: Based on Pressley, M., & Woloshyn, V. (1995). *Cognitive Strategy Instruction That Really Improves Children's Academic Performance*. Cambridge, MA: Brookline Books.

of the knowledge at that point would be reorganized and connected well with other knowledge. “See,” I told the class, “these ideas are real—not just trapped in texts. They can help you study smarter in college.” After a heated discussion, one of the best students said in exasperation, “I’m carrying 18 hours—I don’t have time to *learn* this stuff!” She did not believe that her goal—to survive the 18 hours—could be reached by using time-consuming study strategies, and she might have been right.

EFFORT AND EFFICACY. My student also was concerned about effort. The third condition for applying learning strategies is that students must believe the effort and investment required are reasonable, given the likely return (Winne, 2001). And of course, students must believe they are capable of using the strategies; they must have self-efficacy for using the strategies to learn the material in question (Schunk, 2016). This is related to another condition: Students must have a base of knowledge and/or experience in the area. No learning strategies will help students accomplish tasks that are completely beyond their current understandings.

Reaching Every Student: Teaching How to Learn

Reading is key in all learning in school. Strategy instruction can help many struggling readers—and the earlier students learn useful strategies, the better. Of course, you have to do more than just tell students about the strategy—you have to teach it. Michael Pressley and Vera Woloshyn (1995) developed the Cognitive Strategies Model as a guide for teaching students to improve their metacognitive strategies. Table 9.2 describes the steps in teaching these strategies.

MyLab Education [Self-Check 9.2](#)

PROBLEM SOLVING

PUT YOURSELF IN MY PLACE. You’re interviewing with the district superintendent for a position as a school psychologist. The superintendent is known for his unorthodox interview questions. He hands you a pad of paper and a ruler and says, “Tell me, what is the exact thickness of a single sheet of paper?” •

Connect and Extend to PRAXIS II®

Problem Solving (II, A1)

Be prepared to identify the steps in the general problem-solving process. Describe the techniques that students can employ to build useful representations of problems.

The *Put Yourself in My Place* is a true story. I was asked the paper thickness question in an interview years ago. The answer was to measure the thickness of the entire pad and divide by the number of pages in the pad. I got the answer and the job, but what a tense moment that was. I suppose the superintendent was interested in my ability to solve problems—under pressure!

A **problem** exists when you are searching for a path to reach a goal. Problem solvers often have to set and reach subgoals as they move toward the final solution. For example, if your goal is to drive to the beach, but at the first stop sign you skid through the intersection, you may have to reach a subgoal of fixing your brakes before you can continue toward the original goal (Schunk, 2016). Also, problems can range from *well structured* to *ill structured*, depending on how clear-cut the goals are and how much structure is provided for solving them. Most arithmetic problems are well structured, but finding the right college major or career is ill structured—many different solutions and paths to solutions are possible. Life presents many ill-structured problems (Belland, 2011).

Problem solving is usually defined as formulating new answers, going beyond the simple application of previously learned rules to achieve a goal. Problem solving is what happens when no solution is obvious—when, for example, you can't afford new brakes for the car that skidded on the way to the beach (Mayer & Wittrock, 2006). Some psychologists suggest that most human learning involves problem solving and that helping students become better problem solvers is one of education's greatest challenges (J. R. Anderson, 2015; Greiff et al., 2013).

There is a debate about problem solving. Most psychologists believe that effective problem-solving strategies are specific to the problem area. For example, the problem-solving strategies in mathematics are unique to math; the strategies in art are unique to art, and so on (Tricot & Sweller, 2014). The other side of the debate claims that there are some general problem-solving strategies that can be useful in many areas such as using *analogical reasoning* or *means-ends analysis* (discussed later).

There is evidence for the value of both general and specific strategies. In everyday life, people appear to move between general and specific approaches, depending on the situation and their level of expertise. Early on, when we know little about a problem area or domain, we can rely on general learning and problem-solving strategies to make sense of the situation. As we gain more domain-specific knowledge (particularly *procedural knowledge* about how to do things in the domain), we consciously apply the general strategies less and less; our problem solving becomes more automatic. So to become an expert problem solver in an area, domain-specific skills are the most important to attain (Bokosmaty et al., 2015; Tricot & Sweller, 2014).

A key first step in any problem-solving situation is identifying that a problem exists (and perhaps treating the problem as an opportunity).

Identifying: Problem Finding

Problem identification is not always straightforward. I am reminded of a story about tenants who were angry because the elevators in their building were slow. Consultants hired to “fix the problem” reported that the elevators were no worse than average and improvements would be very expensive. One day, as the building supervisor watched people waiting impatiently for an elevator, he realized that the problem was not slow elevators, but the fact that people were bored; they had nothing to do while they waited. When the boredom problem was identified and seen as an opportunity to improve the “waiting experience,” the simple solution of installing a mirror by the elevator on each floor eliminated complaints. Today people would just pull out their smart phones to deal with the boredom!

Even though problem identification is a critical first step, research indicates that people often “leap” to naming the first problem that comes to mind (“the elevators are too slow!”). Experts in a field are more likely to spend time carefully considering the nature of the problem (Bruning, Schraw, & Norby, 2011). Finding a solvable problem and turning it into an opportunity is the process behind many successful inventions,

MyLab Education Video Example 9.2

Problem solving is a skill these teachers address directly in their classes. In all disciplines, students may need scaffolding as they learn how to identify the problem and understand what is involved in finding a solution.

Problem Any situation in which you are trying to reach some goal and must find a means to do so.

Problem solving Creating new solutions for problems.

such as the ballpoint pen, garbage disposal, appliance timer, alarm clock, self-cleaning oven, and thousands of others.

Once a solvable problem is identified, what next?

Defining Goals and Representing the Problem

Let's take a real problem: The machines designed to pick tomatoes are damaging the tomatoes. What should we do? If we represent the problem as a faulty machine design, then the goal is to improve the machine. But if we represent the problem as a faulty design of the tomatoes, then the goal is to develop a tougher tomato. The problem-solving process follows two entirely different paths, depending on which representation and goal are chosen (Nokes-Malach & Mestre, 2013). To represent the problem and set a goal, you have to *focus attention* on relevant information, *understand the words* of the problem, and *activate the right schema* to understand the whole problem.

STOP & THINK If you have black socks and white socks in your drawer, mixed in the ratio of four to five, how many socks will you have to take out to make sure you have a pair the same color? (Adapted from Sternberg & Davidson, 1982.) •

FOCUSING ATTENTION ON WHAT IS RELEVANT. Representing the problem often requires finding the relevant information and ignoring the irrelevant details. For example, what information was relevant in solving the sock problem in *Stop & Think*? Did you realize that the information about the four-to-five ratio of black socks to white socks is irrelevant? As long as you have only two different colors of socks in the drawer, you will have to remove only three socks before two of them match.

UNDERSTANDING THE WORDS. The second task in representing a problem is understanding the meaning of the words, sentences, and factual information in the problem. So problem solving requires comprehension of the language and relations in the problem. In math word problems, it also involves assigning mathematical operators (addition, division, etc.) to relations among numbers (Jitendra et al., 2009; K. Lee, Ng, & Ng, 2009). All this makes a demand on working memory. For example, the main stumbling block in representing many word problems and problems with fractions is the students' understanding of part-whole relations (Fuchs et al., 2013). Students have trouble figuring out what is part of what, as is evident in this dialogue between a teacher and a first-grader:

Teacher: Pete has three apples. Ann also has some apples. Pete and Ann have nine apples altogether. How many apples does Ann have?

Student: Nine.

Teacher: Why?

Student: Because you just said so.

Teacher: Can you retell the story?

Student: Pete had three apples. Ann also had some apples. Ann had nine apples. Pete also has nine apples. (Adapted from De Corte & Verschaffel, 1985, p. 19)

The student interprets "altogether" (the whole) as "each" (the parts).

A common difficulty for older students is understanding that ratio and proportion problems are based on multiplicative relations, not additive relations (Jitendra et al., 2009). So to solve

$$2 : 14 = ? : 35$$

many students subtract to find the difference between 2 and 14 ($14 - 2 = 12$) and then subtract 12 from 35 to get 23, giving them the (wrong) answer

$$2 : 14 = 23 : 35$$

The real question is about the *proportional* relationship between 2 and 14. How many *times* larger than 2 is 14? The answer: 7 times larger—a multiplicative relationship. So then the real question is “35 is 7 times larger than what number?” The answer is 5 ($7 \times 5 = 35$). So

$$2 : 14 + 5 : 35$$

UNDERSTANDING THE WHOLE PROBLEM. The third task in representing a problem is to assemble all the relevant information and sentences into an accurate understanding or translation of the total problem. This means that students need to form a conceptual model of the problem—they have to understand what the problem is *really asking* (Jonassen, 2003). Consider the example of the trains in *Stop & Think*.

STOP & THINK Two train stations are 50 miles apart. At 2 p.m. one Saturday afternoon, two trains start toward each other, one from each station. Just as the trains pull out of the stations, a bird springs into the air in front of the first train and flies ahead to the front of the second train. When the bird reaches the second train, it turns back and flies toward the first train. The bird continues to do this until the trains meet. If both trains travel at the rate of 25 miles per hour and the bird flies at 100 miles per hour, how many miles will the bird have flown before the trains meet? (Posner, 1973). •

Your interpretation of the problem is called a *translation* because you translate the problem into a schema that you understand. If you translate this as a *distance* problem (activate a distance schema) and set a goal (“I have to figure out how far the bird travels before it meets the oncoming train and turns around, then how far it travels before it has to turn again, and finally add up all the trips back and forth”), then you have a very difficult task on your hands. But there is a better way to structure the problem. You can represent it as a question of *time* and focus on the time the bird is in the air. The solution could be stated like this:

The trains are going the same speed so they will meet in the middle, 25 miles from each station. This will take one hour because they are traveling 25 mph. In an hour, the bird will cover 100 miles because it is flying at 100 miles per hour. Easy!

Research shows that students can be too quick to decide what a problem is asking. Once a problem is categorized—“Aha, it’s a distance problem!”—a particular schema is activated. The schema directs attention to relevant information and sets up expectations for what the right answer should look like. For example, if you use a distance schema in the above problem, the right answer looks like adding up many small distance calculations (Kalyuga, Chandler, Tuovinen, & Sweller, 2001; Reimann & Chi, 1989).

When students lack the necessary schemas to represent problems, they often rely on surface features of the situation and represent the problem incorrectly, like the student who wrote “ $15 + 24 = 39$ ” as the answer to, “Joan has 15 bonus points and Louise has 24. How many more does Louise have?” This student saw two numbers and the word *more*, so he applied the *add to get more* procedure. Focus on surface features often happens when students are taught to search for key words (*more*, *less*, *greater*, etc.), pick a strategy or formula based on the key words (*more* means “add”), and apply the formula. Actually, focusing on surface features gets in the way of forming a conceptual understanding of the whole problem and using the right schema (Fuchs et al., 2014; Van de Walle, Karp, & Bay-Williams, 2010).

When students use the wrong schema, they overlook critical information, use irrelevant information, and may even misread or misremember critical information so that it fits the schema. But when students use the proper schema to represent a problem, they are less likely to be confused by irrelevant information or tricky wording, such as the presence of the word *more* in a problem that really requires *subtraction* (Fenton, 2007). Figure 9.5 gives examples of different ways students might represent a simple

FIGURE 9.5

FOUR DIFFERENT WAYS TO REPRESENT A PROBLEM

A teacher asks, “How many wildlife stamps will Jane need to fill her book if there are three pages and each page holds 30 stamps?” The teacher gives the students supplies such as a squared paper, number lines, and place-value frames and encourages them to think of as many ways as possible to solve the problem. Here are four different solutions, based on four different but correct representations.

mathematics problem. Exposure to different ways of representing and solving problems helps develop mathematical understanding (Star & Rittle-Johnson, 2009).

How can students who lack a good base of knowledge improve their translation and schema selection? To answer this question, we usually have to move to domain-specific problem-solving strategies because schemas are specific to content areas.

TRANSLATION AND SCHEMA TRAINING: DIRECT INSTRUCTION IN SCHEMAS. For students with little knowledge in an area, teachers can begin by directly teaching the necessary schema using demonstration, modeling, and “think-alouds.” As we just saw, ratio/proportion problems like the following are a big challenge for many students.

Ernesto and Dawn worked separately on their social studies projects this weekend. The ratio of the number of hours Ernesto spent on the project to the number of hours Dawn spent on the project was 2:3. If Ernesto spent 16 hours on the project, how many hours did Dawn spend on the project? (Jitendra et al., 2009, p. 257)

The teacher used a “think-aloud” to focus students on the key schema for solving this problem (in this case a *part-part ratio* schema), so she said, “*First*, I figure this is a ratio problem, because it compared the number of hours that Ernesto worked to the number of hours Dawn worked. This is a *part-part ratio* that tells about a multiplicative relationship (2 : 3) between the hours Ernesto and Dawn worked.” The teacher went on to think aloud, “*Next*, I represented the information by. . . . *Finally*, I used the equivalent fractions strategy and. . . .”

The think-aloud demonstration can be followed by providing students with many *worked examples*. In mathematics and physics it appears that in the *early stages* of learning, students benefit from seeing many different kinds of example problems worked out correctly for them (Moreno, Ozogul, & Reisslein, 2011; Pashler, 2007). But before we explore worked examples in the next section, a caution is in order. Students with advanced knowledge improve when they solve new problems, not when they focus on already worked-out examples. Worked examples can actually interfere with the expert’s learning because the examples fill working memory space with information the experts already understand and therefore don’t need. This has been called the *expert reversal*

effect because what works for experts is the *reverse* of what works for beginners (Bokosmaty, Sweller, & Kalyuga, 2015; Kalyuga, Rikers, & Paas, 2012).

TRANSLATION AND SCHEMA TRAINING: WORKED EXAMPLES. Worked examples are useful in many subject areas. In Australia, studying worked examples helped high school students learn geometry, as long as the kind of guidance provided matched the expertise level of the students (Bokosmaty et al., 2015). In Germany, worked examples were effective for eighth graders learning physics (Glogger-Fey et al., 2015). Silke Schworm and Alexander Renkl (2007) used video examples to help student teachers learn how to make convincing arguments for or against a position.

Why are worked examples effective? Part of the answer is in *cognitive load theory*, discussed in the previous chapter. When students lack specific knowledge in domains—for example, fractions or proportions—they try to solve the problems using general strategies such as looking for key words, applying rote procedures, or using trial-and-error. But these approaches put great strain on working memory—there is too much to “keep in mind” at once. And if you find a solution using trial and error, you often don’t know *why* it worked so you haven’t learned how to solve similar problems in the future. In contrast, worked examples chunk some of the steps, provide cues and feedback, focus attention on relevant information, and make fewer demands on memory, so the students can use cognitive resources to understand instead of searching randomly for solutions (Wittwer & Renkl, 2010). It is especially useful if the examples focus on critical features of the problems that students have not yet mastered (Guo, Pang, Yang, & Ding, 2012).

To get the most benefit from worked examples, however, students have to actively engage—just “looking over” the examples is not enough. This is not too surprising when you think about what supports learning and memory. You need to pay attention, process deeply, and connect with what you already know. Students should explain the examples to themselves. This *self-explanation* component is a critical part of making learning from worked examples active, not passive. Examples of self-explanation strategies include trying to predict the next step in a solution, then checking to see if you are right or trying to identify an underlying principle that explains how to solve the problem. In their study with student teachers, Schworm and Renkl (2007) embedded prompts that required the student teachers to think about and explain elements of the arguments they saw on the tape, such as, “Which argumentative elements does this sequence contain? How is it related to Kirsten’s statement?” (p. 289). Students have to be mentally engaged in making sense of the examples, and self-explanation is one key to engagement (R. K. Atkinson & Renkl, 2007; Wittwer & Renkl, 2010).

Another way to use worked examples is to have students compare examples that reach a right answer but are worked out in different ways. What is the same about each solution? What is different? Why? (Rittle-Johnson & Star, 2007). Also, worked-out examples should deal with one source of information at a time rather than having students move between text passages, graphs, tables, and so on. The cognitive load will be too heavy for beginners if they have to integrate many sources of information to make sense of the worked examples (Bokosmaty et al., 2015). In addition, alternating between studying worked examples and actually solving problems can help students apply and extend what they are learning (Renkl, 2011).

Worked examples can serve as analogies or models for solving new problems. But beware. Without explanations and coaching, novices may remember the surface features of a worked example or case instead of the deeper meaning or the structure. It is the meaning or structure, not the surface similarities, that helps in solving new, analogous problems (Gentner, Loewenstein, & Thompson, 2003; Goldstone & Day, 2012). I have heard students complain that the test preparation problems in their math classes were about boats and river currents, but the test asked about airplanes and wind speed. They protested, “There were no problems about boats on the test, and we never studied airplanes in class!” In fact, the problems about wind on the test were solved in exactly the same way as the “boat” problems, but the students were focusing only on the surface features—the type of vehicle. One way to overcome this tendency is to have students

compare examples or cases so they can develop a problem-solving schema that captures the common structure, not the surface features, of the cases (Gentner et al., 2003).

WORKED EXAMPLES AND EMBODIED COGNITION. Using more learning channels together also supports learning with worked examples. For instance, when students traced figures with their index finger, as shown in Figure 9.6, they learned more, perhaps because they were using vision, touch, and movement together to engage with the examples (Hu, Ginns, & Bobis, 2015). This approach to engaged learning is consistent with a recent theory called **embodied cognition**, which is based on the assumption that “the way we think about and represent information reflects the fact that we need to interact with the world” (Ashcraft & Radvansky, 2010, p. 32). These interactions occur through our senses and bodies, and the way our bodies interact with the world to achieve our goals affects our thinking. In other words, our cognitive processes have deep roots in the interactions of our bodies with the real world—what develops cognitively depends on our sensorimotor engagement with the world. In some ways, this perspective is similar to Piaget’s idea that thinking emerges early on from the infant’s sensorimotor interaction in the world. Instead of being just simple conduits for outside world sounds and images, our senses and motor responses are central to how we think. So we have to understand how our physical body interacts with the world in order to understand our mind (Chandler & Tricitt, 2015; Wilson, 2002). Observational learning is an example. Watching someone perform an action activates the same areas of the brain in observers that would be involved in performing that action themselves—almost as if the brain learns by mentally rehearsing the action. So using models, gestures and movement, and other kinds of actions and movements can support learning (de Koning & Tabbers, 2011; Novack, & Goldin-Meadow, 2015).

How else might students develop the schemas they will need to represent problems in a particular subject area? Mayer (1983) has recommended giving students practice in the following: (1) recognizing and categorizing a variety of problem types; (2) representing

FIGURE 9.6

ENGAGING WITH WORKED EXAMPLES: TRACING SOLUTIONS

When students use multiple channels to engage with worked examples, their learning is better.

Question: What is the value of x ?

Embodied cognition

Theory stating that cognitive processes develop from real-time, goal-directed interactions between humans and their environment.

problems, either concretely in pictures, symbols, or graphs, or in words; and (3) selecting relevant and irrelevant information in problems.

THE RESULTS OF PROBLEM REPRESENTATION. The problem representation stage of problem solving has two main outcomes, as shown in Figure 9.7. If your representation of the problem suggests an immediate solution, your task is done. In one sense, you haven't really solved a new problem; you have simply recognized the new problem as a "disguised" version of an old problem that you already knew how to solve. This has been called **schema-driven problem solving**. In terms of Figure 9.7, you can use the schema-activated route and proceed directly to a solution.

But what if you have no existing way of solving the problem or your activated schema fails? Time to search for a solution!

Searching for Possible Solution Strategies

In conducting your search for a solution, you have available two general kinds of procedures: algorithmic and heuristic. Both of these are forms of procedural knowledge (Schraw, 2006).

ALGORITHMS. An **algorithm** is a step-by-step prescription for achieving a goal. It usually is domain specific; that is, it is tied to a particular subject area. In solving a problem, if you choose an appropriate algorithm (e.g., to find the mean, you add all the scores, then divide by the number of scores) and implement it properly, a right answer is guaranteed. Unfortunately, students often apply algorithms unsystematically, trying out one first, and then another. They may even happen on the right answer, but not understand how they got there, or they may forget the steps they used to find the answer. For some students, applying algorithms haphazardly could be an indication that formal operational thinking and the ability to work through a set of possibilities systematically (as described by Piaget) are not yet developed. But many problems cannot be solved by algorithms. What then?

FIGURE 9.7

THE PROBLEM-SOLVING PROCESS

There are two paths to a solution. In the first, the correct schema is activated and the solution is apparent—the new problem is an old one in disguise. But if no schema works, searching and testing may provide a path to a solution.

Schema-driven problem solving Recognizing a problem as a "disguised" version of an old problem for which one already has a solution.

Algorithm Step-by-step procedure for solving a problem; prescription for solutions.

HEURISTICS. A heuristic is a general strategy that might lead to the right answer (Schoenfeld, 2011). Because many of life's problems (careers, relationships, etc.) are not straightforward and have no apparent algorithms, the discovery or development of effective heuristics is important (Korf, 1999). Let's examine a few.

In **means-ends analysis**, the problem is divided into a number of intermediate goals or subgoals, and then a means of solving each intermediate subgoal is figured out. For example, writing a 20-page term paper can loom as an insurmountable problem for some students. They would be better off breaking this task into several intermediate goals, such as selecting a topic, locating sources of information, reading and organizing the information, making an outline, and so on. As they attack a particular intermediate goal, they may find that other goals arise. For example, locating information may require that they find someone to refresh their memory about using the library computer search system. Keep in mind that psychologists have yet to discover an effective heuristic for students who are just starting their term paper the night before it is due.

Some problems lend themselves to a **working-backward strategy**, in which you begin at the goal and move back to the unsolved initial problem. Working backward is sometimes an effective heuristic for solving geometry proofs. It can also be a good way to set intermediate deadlines ("Let's see, if I have to submit this chapter in 4 weeks, I should have a first draft finished by the 11th, and that means I better stop searching for new references and start writing by . . .").

Another useful heuristic is **analogical thinking** (Anderson, 2015; Gentner et al., 2003), which limits your search for solutions to situations that have something in common with the one you currently face. When submarines were first designed, for example, engineers had to figure out how battleships could determine the presence and location of vessels hidden in the depths of the sea. Studying how bats solve an analogous problem of navigating in the dark led to the invention of sonar. Take note, however, that to use analogies effectively, you must focus on meaning and not surface similarities, so focusing on bats' appearance would not have helped to solve the communication problem.

The possible analogies students bring to the classroom are bound to vary, based on their experience and culture. For example, Zhe Chen and his colleagues wondered if college students might use familiar folk tales—one kind of cultural knowledge—as analogies to solve problems (Z. Chen, Mo, & Honomichl, 2004). That is just what happened. Chinese students were better at solving a problem of weighing a statue because the problem was similar to their folk tale about how to weigh an elephant (by water displacement). American students were better at solving a problem of finding the way out of a cave (leaving a trail) by using an analogy to Hansel and Gretel, a common European American folk tale.

Putting your problem-solving plan into words and giving reasons for selecting it can lead to successful problem solving. You may have discovered the effectiveness of this **verbalization** process accidentally, when a solution popped into your head as you were explaining a problem to someone else.

Anticipating, Acting, and Looking Back

After representing the problem and exploring possible solutions, the next step is to select a solution and anticipate the consequences. For example, if you decide to solve the damaged tomato problem by developing a tougher tomato, how will consumers react? If you take time to learn a new graphics program to enhance your term paper (and your grade), will you still have enough time to finish the paper?

After you choose a solution strategy and implement it, evaluate the results by checking for evidence that confirms or contradicts your solution. Many people tend to stop working before they reach the best solution and simply accept an answer that works in some cases. In mathematical problems, evaluating the answer might mean applying a checking routine, such as adding to check the result of a subtraction problem. Another possibility is estimating the answer. For example, if the computation was 11×21 , the answer should be around 200, because 10×20 is 200. A student who reaches an answer of 2,311 or 32 or 562 should quickly realize these answers cannot be correct. Estimating

Heuristic General strategy used in attempting to solve problems.

Means-ends analysis Heuristic in which a goal is divided into subgoals.

Working-backward strategy Heuristic in which you start with the goal and move backward to solve the problem.

Analogical thinking Heuristic in which one limits the search for solutions to situations that are similar to the one at hand.

Verbalization Putting your problem-solving plan and its logic into words.

an answer is particularly important when students rely on calculators or computers, because they cannot go back and spot an error in the figures.

Factors That Hinder Problem Solving

Sometimes problem solving requires looking at things in new ways. People may miss out on a good solution because they fixate on conventional uses for materials. This difficulty is called **functional fixedness** (Duncker, 1945). In your everyday life, you may often exhibit functional fixedness. Suppose a screw on a dresser-drawer handle is loose. Will you spend 10 minutes searching for a screwdriver, or will you fix it with a ruler edge or a dime?

Another kind of fixation that blocks effective problem solving is **response set**, getting stuck on one way of representing a problem. Try this:

In each of the four matchstick arrangements below, move only one stick to change the equation so that it represents a true equality such as $V = V$.

$$V = VII \quad VI = XI \quad XII = VII \quad VI = II$$

You probably figured out how to solve the first example quite quickly. You simply move one matchstick from the right side over to the left to make $VI = VI$. Examples two and three can also be solved without too much difficulty by moving one stick to change the V to an X or vice versa. But the fourth example (taken from Raudsepp & Haugh, 1977) probably has you stumped. To solve this problem, you must change your response set or switch schemas, because what has worked for the first three problems will not work this time. The answer here lies in changing from Roman numerals to Arabic numbers and using the concept of square root. By overcoming response set, you can move one matchstick from the right to the left to form the symbol for square root; the solution reads $\sqrt{1} = 1$, which is simply the symbolic way of saying that the square root of 1 equals 1.

Recently, a creative reader of this text emailed some other solutions. Jamaal Allan, then a masters student at Pacific University, pointed out that you could use any of the matchsticks to change the $=$ sign to $\neq$. Then, the last example would be $V \neq II$ or 5 does not equal 2, an accurate statement. He suggested that you also might move one matchstick to change $=$ to $<$ or $>$ and the statements would still be true (but not equalities as specified in the problem above). Bill Wetta, a student at Ashland University, offered another solution that used both Arabic and Roman numerals. You can move one matchstick to make the first V an X . Then $VI = II$ becomes $XI = II$, or eleven (in Roman numerals) equals 11 (in Arabic numerals). Just this morning I received another creative approach from Ray Partlow, an educational psychology student in Newark, Ohio. He noted, "Simply remove a matchstick from the V from the left-hand side, and place it directly on top of the I , getting $II = II$." Covering one matchstick with another opens up a whole new set of possibilities! Can you come up with any other solutions? Be creative!

SOME PROBLEMS WITH HEURISTICS. We often apply heuristics automatically to make quick judgments; that saves us time in everyday problem solving. The mind can react automatically and instantaneously, but the price we often pay for this efficiency may be bad problem solving, which can be costly. Making judgments by invoking stereotypes leads even smart people to make dumb decisions. For example, we might use **representativeness heuristics** to make judgments about possibilities based on our prototypes—what we think is representative of a category. Consider this:

If I ask you whether a slim, short stranger who enjoys poetry is more likely to be a truck driver or an Ivy League classics professor, what would you say?

You might be tempted to answer based on your prototypes of truck drivers or professors. But consider the odds. With about 10 Ivy League schools and 4 or so classics professors per school, we have 40 professors. Say 10 are both short and slim, and half of those like poetry—we are left with 5. But there are at least 3.5 million truck drivers in the United States. If only 1 in every 5,000 of those truck drivers were short, slim poetry lovers, we would have 700 truck drivers who fit the description. With 700 truck drivers versus 5 professors, it is 140 times more likely that our stranger is a truck driver (Myers, 2005).

Functional fixedness

Inability to use objects or tools in a new way.

Response set Rigidity; the tendency to respond in the most familiar way.

Representativeness heuristic

Judging the likelihood of an event based on how well the events match your prototypes—what you think is representative of the category.

Teachers and students are busy people, and they often base their decisions on what they have in their minds at the time. When judgments are based on the availability of information in our memories, we are using the **availability heuristic**. If instances of events come to mind easily, we think they are common occurrences, but that is not necessarily the case; in fact, it is often wrong. People remember vivid stories and quickly come to believe that such events are the norm, but again, they often are wrong. For example, after you watch a few TV programs during “Shark Week” you may overestimate how many people actually are killed by sharks each year. Data may not support a judgment, but **belief perseverance**, or the tendency to hold on to our beliefs, even in the face of contradictory evidence, may make us resist change.

The **confirmation bias** is the tendency to search for information that confirms our ideas and beliefs: This arises from our eagerness to get a good solution. You have often heard the saying “Don’t confuse me with the facts.” This aphorism captures the essence of the confirmation bias. Most people seek evidence that supports their ideas more readily than they search for facts that might refute them. For example, once you decide to buy a certain car, you are likely to notice reports about the good features of the car you chose, not the good news about the cars you rejected. Our automatic use of heuristics to make judgments, our eagerness to confirm what we like to believe, and our tendency to explain away failure combine to generate *overconfidence*. Students usually are overconfident about how fast they can get their papers written; it typically takes twice as long as they estimate (Buehler, Griffin, & Ross, 1994). In spite of their underestimation of their completion time, they remain overly confident of their next prediction.

The *Guidelines: Applying Problem Solving* give some ideas for helping students become good problem solvers.

Availability heuristic

Judging the likelihood of an event based on what is available in your memory, assuming those easily remembered events are common.

Belief perseverance The tendency to hold on to beliefs, even in the face of contradictory evidence.

Confirmation bias Seeking information that confirms our choices and beliefs, while ignoring disconfirming evidence.

GUIDELINES

Applying Problem Solving

Ask students if they are sure they understand the problem.

Examples

1. Can they separate relevant from irrelevant information?
2. Are they aware of the assumptions they are making?
3. Encourage them to visualize the problem by diagramming or drawing it.
4. Ask them to explain the problem to someone else. What would a good solution look like?

Encourage attempts to see the problem from different angles.

Examples

1. Suggest several different possibilities yourself, and then ask students to offer some.
2. Give students practice in taking and defending different points of view on an issue.

Let students do the thinking; don’t just hand them solutions.

Examples

1. Offer individual problems as well as group problems, so that each student has the chance to practice.

2. Give partial credit if students have good reasons for “wrong” solutions to problems.
3. If students are stuck, resist the temptation to give too many clues. Let them think about the problem overnight.

Help students develop systematic ways of considering alternatives.

Examples

1. Think out loud as you solve problems.
2. Ask, “What would happen if?”
3. Keep a list of suggestions.

Teach heuristics.

Examples

1. Use analogies to solve the problem of limited parking in the downtown area. How are other “storage” problems solved?
2. Use the working-backward strategy to plan a party.

Expert Knowledge and Problem Solving

Most psychologists agree that effective problem solving is based on having an ample store of knowledge about the problem area (Belland, 2011; Schoenfeld, 2011). To solve the matchstick problem, for example, you had to understand Roman and Arabic numbers as well as the concept of square root. You also had to know that the square root of 1 is 1. Let's take a moment to examine this expert knowledge.

KNOWING WHAT IS IMPORTANT. Experts know where to focus their attention. For example, knowledgeable baseball fans (I am told) pay attention to the moves of the shortstop to learn if the pitcher will throw a fastball, curveball, or slider. But those with little knowledge about baseball may never see the movements of the shortstop, unless a hit is headed toward that part of the field (Bruning, Schraw, & Norby, 2011). In general, experts know what to pay attention to when judging a performance or product such as an Olympic high dive or a prize-winning chocolate cake. To nonexperts, most good dives or cakes look about the same, unless of course they “flop”!

MEMORY FOR PATTERNS AND ORGANIZATION. The modern study of expertise began with investigations of chess masters (De Groot, 1965; D. P. Simon & Chase, 1973). Results indicated that masters can quickly recognize about 50,000 different arrangements of chess pieces. They can look at one of these patterns for a few seconds and remember where every piece on the board was placed. It is as though they have a “vocabulary” of 50,000 patterns. Michelene Chi (1978) demonstrated that third- through eighth-grade chess experts had a similar ability to remember chess piece arrangements. For all the masters, patterns of pieces are like words. If you were shown any word from your vocabulary store for just a few seconds, you would be able to remember every letter in the word in the right order (assuming you could spell the word). But a series of letters arranged randomly is hard to remember, as you saw in Chapter 8. An analogous situation holds for chess masters. When chess pieces are placed on a board randomly, masters are no better than average players at remembering the positions of the pieces. The master's memory is for patterns that make sense or could occur in a game. So expertise in chess is based on extensive domain-specific knowledge of possible patterns and moves stored in long-term memory.

A similar phenomenon occurs in other fields. There may be an intuition about how to solve a problem based on recognizing patterns and knowing the “right moves” for those patterns. Experts in physics, for example, organize their knowledge around central principles (e.g., Boyle's or Newton's laws), whereas beginners organize their smaller amounts of physics knowledge around the specific details stated in the problems (e.g., levers or pulleys) (K. A. Ericsson, 1999; Fenton, 2007).

PROCEDURAL KNOWLEDGE. In addition to representing a problem very quickly, experts know what to do next and can do it. They have a large store of *productions* or if-then schemas about what action to take in various situations. So, the steps of understanding the problem and choosing a solution happen simultaneously and fairly automatically (K. A. Ericsson & Charness, 1999). Of course, this means that experts must have many, many schemas available. A large part of becoming an expert is simply acquiring a great store of *domain knowledge* or knowledge that is particular to a field. To do this, you must encounter many different kinds of problems in that field, observe others solving problems, and practice solving many yourself. In fact, “expertise in any substantial domain requires years of practice with the intention of improving performance” (Tricot & Sweller, 2014, p. 275). Some estimates are that it takes 10 years or 10,000 hours of deliberate, focused, sustained practice to become an expert in most fields (A. Ericsson, 2011; K. A. Ericsson & Charness, 1994; H. A. Simon, 1995). Experts' rich store of knowledge is elaborated and well practiced, so that it is easy to retrieve from long-term memory when needed (J. R. Anderson, 2015).

PLANNING AND MONITORING. Experts spend more time analyzing problems, drawing diagrams, breaking large problems down into subproblems, and making plans. A novice might begin immediately—writing equations for a physics problem or drafting the

first paragraph of a paper—but experts plan out the whole solution and often make the task simpler in the process. As they work, experts monitor progress, so time is not lost pursuing dead ends or weak ideas (Schunk, 2016). We all can be experts in one area—studying. The *Guidelines: Becoming an Expert Student* provide a ideas for you and your students.

So what can we conclude? Experts (1) know where to focus their attention; (2) perceive large, meaningful patterns in given information and are not confused by surface features and details; (3) hold more information in working and long-term memories, in

GUIDELINES

Becoming an Expert Student

Be clear about your goals in studying.

Examples

1. Target a specific number of pages to read and outline.
2. Write the introduction section of a paper.

Make sure you have the necessary declarative knowledge (facts, concepts, ideas) to understand new information.

Examples

1. Keep definitions of key vocabulary available as you study.
2. Use your general knowledge. Ask yourself, "What do I already know about _____?"
3. Build your vocabulary by learning two or three new words a day using them in everyday conversation.

Find out what type of test the teacher will give (essay, short answer), and study the material with that in mind.

Examples

1. For a test with detailed questions, practice writing answers to possible questions.
2. For a multiple-choice test, use mnemonics to remember definitions of key terms.

Make sure you are familiar with the organization of the materials to be learned.

Examples

1. Preview the headings, introductions, topic sentences, and summaries of the text.
2. Be alert for words and phrases that signal relationships, such as *on the other hand*, *because*, *first*, *second*, *however*, *since*.

Know your own cognitive skills, and use them deliberately.

Examples

1. Use examples and analogies to relate new material to something you care about and understand well, such as sports, hobbies, or films.
2. If one study technique is not working, try another—the goal is to stay involved, not to use any particular strategy.
3. If you start to daydream, stand up from your desk and face away from your books, but don't leave. Then sit back down and study.

Study the right information in the right way.

Examples

1. Be sure you know exactly what topics and readings the test will cover.
2. Spend your time on the important, difficult, and unfamiliar material that will be required for the test or assignment. Resist the temptation to go over what you already know well, even if that feels good.
3. Keep a list of the parts of the text that give you trouble, and spend more time on those pages.
4. Process the important information thoroughly by using mnemonics, forming images, creating examples, answering questions, making notes in your own words, and elaborating on the text. Do not try to memorize the author's words—use your own.

Monitor your own comprehension.

Examples

1. Use questioning to check your understanding.
2. When reading speed slows down, decide if the information in the passage is important. If it is, note the problem so you can reread or get help to understand. If it is not important, ignore it.
3. Check your understanding by working with a friend and quizzing one another.

Manage your time.

Examples

1. When is your best time for studying? Morning, late night? Study your most difficult subjects then.
2. Study in shorter rather than longer blocks, unless you are really engaged and making great progress.
3. Eliminate time wasters and distractions. Study in a room without a television or your roommate, then turn off your phone and stay off social media—maybe even off the Internet altogether.
4. Use bonus time—take your educational psychology notes to the doctor's office waiting room or laundry room. You will use time well and avoid reading old magazines.

Based on ideas from: ucc.vt.edu/study_skills_resources and Wong, L. (2015). *Essential Study Skills* (8th ed.) Stamford, CT: Cengage.

part because they have organized the information into meaningful and interconnected schemas and procedures; (4) take a great deal of time to analyze a given problem; (5) have automatic procedures for accomplishing pieces of the problem; and (6) are better at monitoring their performance (Richey & Nokes-Malach, 2015). One consequence of developing expertise is that experts forget how difficult it was to learn something and how long it took. As a teacher, you will have to be sensitive about what it means for students to not understand. Sometimes the best teacher is another student who has just mastered the material, not an expert who cannot remember what it was like not to know.

When the area of problem solving is fairly well defined, such as chess or physics or computer programming, then these skills of expert problem solvers hold fairly consistently. In these kinds of domains, even if students do not have the extensive background knowledge of experts, they can learn to approach the problem like an expert by taking time to analyze the problem, focusing on key features, using the right schema, and not trying to force old but inappropriate solutions on new problems (Belland, 2011). But when the problem-solving area is less well defined and has fewer clear underlying principles, such as problem solving in economics or psychology, then the differences between experts and novices are not as clear-cut (Alexander, 1992).

MyLab Education Self-Check 9.3

CRITICAL THINKING AND ARGUMENTATION

Virtually every article I read before writing this section began with a claim about how essential critical thinking is today. Critical thinking skills are useful in almost every life situation—even in evaluating the media and political ads that constantly bombard us (Huber & Kuncel, 2016). When you see a group of gorgeous people extolling the virtues of a particular brand of orange juice as they frolic in skimpy bathing suits, you must decide if sex appeal is a relevant factor in choosing a fruit drink (remember Pavlovian advertising from Chapter 7). **Critical thinking** is “an effortful and deliberate cognitive process that entails reflection on and evaluation of available evidence” (Wentzel, 2014, p. 579).

The goal of critical thinking is to influence beliefs and guide actions. But what if you have the cognitive skills to make reasoned judgments and still don’t use these skills in a given situation to evaluate claims by politicians or Web sites? You need the disposition to act and bring your critical thinking cognitive skills to those specific issues. *The Delphi Report*, written by a panel of experts who study critical thinking, addressed this by listing three categories of skills necessary for critical thinking: *cognitive skills* (interpretation, analysis, evaluation of claims and arguments, self regulation, etc.); *affective dispositions* (inquisitiveness, open-mindedness, honesty in facing your own biases, ability to understand the views of others, willingness to reconsider and revise your views, etc.); and *approaches to specific problems* (diligence in seeking and focusing on relevant information, clarity in stating the questions, reasonableness in selecting and applying criteria, etc.) (Abrami et al., 2015). So critical thinking involves intentionally bringing your clearest thinking to shape your beliefs and direct your actions.

What Critical Thinkers Do: Paul and Elder Model

Richard Paul and Linda Elder (2014; Elder & Paul, 2012) suggest the model in Figure 9.8 as a way of describing what critical thinkers actually do. As you can see, at the center of critical thinking are *the elements* of reasoning, which entail drawing conclusions based on reasons. But to reason well—to think critically—we should apply *the standards* such as clarity, accuracy, logic, and fairness, as indicated in Figure 9.8. With practice in clear, accurate, logical (etc.) reasoning, we develop *intellectual traits* such as humility, integrity, perseverance, and confidence.

Research results are clear: Critical thinking skills and the dispositions to apply those skills can be taught at all grade levels (Abrami et al., 2015). So how would you do that

Connect and Extend to PRAXIS II®

Thinking Skills (II, A1)

A nearly universal goal of educational programs across the country is the development of thinking skills. Describe what a teacher can do to cultivate these skills in the classroom. Search for *Teaching Thinking Skills* at edutopia.org for more ideas.

Critical thinking Evaluating conclusions by logically and systematically examining the problem, the evidence, and the solution.

FIGURE 9.8

PAUL AND ELDER'S MODEL OF CRITICAL THINKING

Critical thinkers routinely apply the intellectual standards to the elements of reasoning to develop intellectual traits.

Source: Paul, R., & Elder, L. (2012). *Critical Thinking: Tools for Taking Charge of Your Learning and Your Life* (3rd ed., p. 58). Upper Saddle River, NJ: Pearson. Reprinted and Electronically reproduced by permission of Pearson Education Inc. Upper Saddle River, New Jersey.

in your classes? When he analyzed over 340 interventions to teach critical thinking with students ages 6 through adulthood in primary through graduate schools, three elements emerged as effective: dialogue, authentic instruction, and mentorship.

- **Dialogue:** Teachers pose questions and encourage students to dialogue through whole class and small group discussion, debates, Socratic dialogue, or written exchanges.
- **Authentic Instruction:** Teachers focus the dialogue on problems that make sense to the students using role-plays, simulations, case studies, or ethical dilemmas, for example.
- **Mentorship:** One-to-one mentoring for students from teachers, coaches, or other adults also supports the development of critical thinking (Abrami et al., 2015).

No matter what approach you use to develop critical thinking, it is important to follow up with additional practice. One lesson is not enough. For example, if your class examined a particular historical document to determine if it reflected bias or propaganda, you should follow up by analyzing other written historical documents, contemporary advertisements, or news stories. Unless thinking skills become overlearned and relatively automatic, they are not likely to be transferred to new situations (Mayer & Wittrock, 2006). Instead, students will use these skills only to complete the lesson in social studies, not to evaluate the claims made by friends, Web sites, politicians, car manufacturers, sales people, or diet plans.

MyLab Education
Video Example 9.3

The students in this video are presenting various formulas for calculating the volume of a sphere. Notice the critical thinking skills involved as students analyze and evaluate formulas presented by classmates. Also notice the role of the teacher's questions.

Applying Critical Thinking in Specific Subjects

Critical thinking could be useful in any subject. But many critical thinking skills are specific to a particular subject and serve to guide actions in that subject (Huber & Kuncel, 2016). For example, to teach history, Jeffrey Nokes and his colleagues investigated (1) using traditional texts versus multiple readings and (2) direct teaching of critical thinking skills versus no direct teaching of critical thinking skills (Nokes, Dole, & Hacker, 2007). The multiple texts included historical fiction, excerpts from speeches, government documents, photographs, charts and historical data, and short sections from texts. The history critical thinking skills taught were:

- **Sourcing:** Looking at the source of the document before reading and using that information to help interpret and make inferences about the reading. Is the source biased? Can I trust it?
- **Corroboration:** Making connections between the information in different texts and noting similarities and contradictions.
- **Contextualization:** Understanding the time, place, people, and culture that comprise the context for the event, with all the political and social forces that might be operating.

Students who learned with multiple texts instead of traditional textbooks actually learned more history content. Also, students were able to learn and apply two of the three critical thinking skills, *sourcing* and *corroboration*, when they were *directly taught* how to use the skills. Contextualization proved more difficult, perhaps because the students lacked the background knowledge to fill in contextual information. So critical thinking for specific subjects can be taught along with the subject. But as you can see in the *Point/Counterpoint*, educators don't agree about the best way to foster critical thinking in schools.

Argumentation

The ability to construct and defend a position is essential in mathematics, physical and social sciences, politics, persuasive writing, and critical thinking, to name just a few areas. Both Piaget and Vygotsky would agree that cognitive development is supported by social interactions, dialogue, challenging misunderstandings, and argument. Like critical thinking, **argumentation**—the process of constructing and critiquing arguments—is considered an important 21st Century skill and is reflected in the Common Core Standards (Asterhan & Schwarz, 2016).

TWO STYLES OF ARGUMENTATION. There are two styles of argumentation—*disputative* and *deliberative*. The heart of *disputative argumentation* is supporting your position with evidence and understanding and then refuting your opponent's claims and evidence. It is a competitive process where the goal is to convince an opponent to switch sides. The basic question is *who* is right. With *deliberative argumentation*, the goal is to collaborate in comparing, contrasting, and evaluating alternatives, then arrive at a constructive conclusion. The basic question is *which idea* is right (Asterhan & Babichenko, 2015). Both kinds of argumentation are difficult. Students often concede right away or else they hold on to their initial beliefs without engaging in the argument. But true learning comes with considering, understanding, and refuting arguments, then improving knowledge based on a consideration of the evidence (Asterhan & Babichenko, 2015).

Children are not good at argumentation, adolescents are a bit better, and adults are better still, but not perfect. Children don't pay very much attention to the claims and evidence of the other person in the debate. Adolescents understand that their opponent in a debate has a different position, but they tend to spend much more time presenting their own position than they do trying to understand and critique their opponent's claims. It is as if the adolescents believe "winning an argument" means making a better

Argumentation The process of debating a claim with someone else.

POINT/COUNTERPOINT: Should Schools Teach Critical Thinking and Problem Solving?

The question of whether schools should focus on process or content, higher-order thinking skills or academic information has been debated for years. Some educators suggest that students must be taught how to think, while other educators assert that students cannot learn to “think” in the abstract. They must be thinking about something—some content. Should teachers focus on content knowledge or critical thinking?

POINT ▶ **Problem solving and critical thinking can and should be taught.** In a special issue of *Educational Psychology Review*, Karen Murphy and her colleagues (2014) made this claim: “Perhaps one of the most important aims of formal education is to equip students with the ability to think critically and analytically about complex topics” (p. 561). This claim is not new, Murphy says. It goes back at least to philosophers before Socrates. But today educators and policy makers argue strongly for investing in programs and practices that teach critical thinking to children and adolescents. Closer to home for you, Peter Facione (2011) claims that critical thinking is related to GPA in college and to reading comprehension. How can students learn to think critically? Some educators recommend teaching thinking skills directly with widely used techniques such as the Productive Thinking Program or CoRT (Cognitive Research Trust). Other researchers argue that learning computer programming languages will improve students’ minds and teach them how to think logically. There is evidence that attending college improves general critical thinking skills and dispositions even without specific interventions fostering critical thinking (Huber & Kuncel, 2016).

COUNTERPOINT ▶ **Critical thinking and problem-solving skills do not transfer.** According to E. D. Hirsch, a vocal critic of critical thinking programs:

But whether such direct instruction of critical thinking or self-monitoring does in fact improve performance is a subject of debate in the research community. For instance, the research regarding critical thinking is not reassuring. Instruction in critical thinking has been going on in several countries for over a hundred years. Yet researchers found that students from nations as varied as Israel, Germany, Australia, the Philippines, and the United States, including those who have been taught critical thinking continue to fall into logical fallacies. (1996, p. 136)

The CoRT program has been used in over 5,000 classrooms in 10 nations. But Polson and Jeffries (1985) report that “after 10 years of widespread use we have no adequate evidence concerning the effectiveness of the program” (p. 445). A focus on general critical thinking skills is wasteful when so many of the important skills are specific to a particular domain and when general critical thinking skills tend to develop on their own (Huber & Kuncel, 2016).

Beware of Either/Or One clear message from current research on learning is that both subject-specific knowledge and learning strategies are important. Students today need to be critical consumers of all kinds of knowledge, but critical thinking alone is not enough. Students need the knowledge, vocabulary, and concepts to understand what they are reading, seeing, and hearing. The best teachers can teach both math content and how to learn math at the same time and can provide instruction in both history and how to critically assess history sources.

presentation, but they don’t appreciate the need to understand and weaken the opponent’s claims (Kuhn & Dean, 2004; Nussbaum, 2011). Children and adolescents focus more on their own positions because it is too demanding to remember and process both their own and their opponent’s claims and evidence at the same time—the *cognitive load* is just too much. In addition, argumentation skills are not natural. They take both time and instruction to learn (Kuhn, Goh, Iordanou, & Shaenfield, 2008; Udell, 2007).

But what has to be learned? In *disputative* argumentation, to make a case while understanding and refuting the opponent’s case, you must be aware of what you are saying, what your opponent is saying, and how to refute your opponent’s claims. This

takes planning, evaluating how the plan is going, reflecting on what the opponent has said, and changing strategies as needed—in other words, *metacognitive knowledge and skills for argumentation*. Deanna Kuhn and her colleagues (2008) designed a process for developing metacognitive argumentation skills. They presented a sixth-grade class with the following dilemma.

The Costa family has moved to the edge of town from far away Greece with their 11-year-old son Nick. Nick was a good student and soccer player back home in Greece. Nick's parents have decided that in this new place, they want to keep Nick at home with them, and not have him be at the school with the other children. The family speaks only Greek, and they think Nick will do better if he sticks to his family's language and doesn't try to learn English. They say they can teach him everything he needs at home. What should happen? Is it okay for the Costa family to live in the town but keep Nick at home, or should they be required to send their son to the town school like all the other families do? (p. 1313)

Based on their initial position on the dilemma, the 28 students in the class were divided into two groups—"Nick should go to school" or "Nick should be taught at home." These two groups were divided again into same-gender pairs and all the "Nick should go to school" pairs moved to a room next door to their class. For about 25 minutes, each pair from one side "debated" a pair in the other room using instant messaging (IM). Later in the week the process was repeated, but with different pairs debating. In all, there were seven IM debates, so every "go to school" pair debated every "stay home" pair over several weeks. After four of the seven sessions, the pairs were given a transcript of the dialogue from their last debate, along with worksheets that scaffolded their *reflection* on their own arguments or the arguments of their opponents. The students evaluated their arguments and tried to improve them, with some adults coaching. These reflective sessions were repeated three times.

Next, there was a "showdown" debate—the entire "go to school" team debated the entire "stay home" team via one computer per team and a smart board. For this debate, half of the members of each team prepared as experts on their position and half as experts *on the opponent's arguments*. After winter break and again after spring break, the whole process was repeated with new dilemmas.

So what happened? The process improved the skill of disputative argumentation—competitive debating. The pairs, IM, and reflection strategies were successful for most students in helping them take into account the opponent's position and create strategies for rebutting the opponent's arguments. Working in pairs seemed to be especially helpful. When adolescents and even adults work alone, they often do not create effective counterarguments and rebuttals (Kuhn & Franklin, 2006).

Kuhn's study focused on disputative argumentation—a classic competitive debate style. But what about deliberative, collaborative argumentation? Recently Christa Asterhan and her colleagues have contrasted deliberative argumentation with disputative argumentation and found that the latter, collaborative approach was better for learning subject matter and for changing beliefs. Maybe the debate style of disputative argumentation focuses students on winning and on how they perform, so they are more resistant to change—and learning often requires change (Asterhan & Schwarz, 2016).

LESSONS FOR TEACHERS. It seems that to improve students' debating and persuasion skills, to help them *learn to argue*, disputative argumentation is a good approach. The strategies developed by Kuhn are useful here. But to learn subject matter, to *argue to learn*, deliberative argumentation makes sense. With this approach teachers encourage students to discuss and dispute in order to construct the best understanding based on evidence.

TEACHING FOR TRANSFER

STOP & THINK Think back for a moment to one of your high school classes in a subject that you have not studied in college. Imagine the teacher, the room, the textbook. Now remember what you actually learned in class. If it was a science class, what were some of the formulas you learned? Oxidation reduction? Boyle's law? •

If you are like most of us, you may remember *that* you learned these things, but you will not be quite sure exactly *what* you learned. Were those hours wasted? This question relates to the important topic of learning transfer. Let's begin with a definition of *transfer*.

Whenever something previously learned influences current learning or when solving an earlier problem affects how you solve a new problem, **transfer** has occurred. Shana Carpenter (2012) defines transfer simply as “the application of learned information to novel contexts” (p. 279). So *transfer* is doing something new, not just reproducing a previous application of the information. If students learn a mathematical principle in one class and use it to solve a physics problem days or weeks later in another class, then transfer has taken place. However, the effect of past learning on present learning is not always positive. Functional fixedness and response set (described earlier in this chapter) are examples of negative transfer because they are attempts to apply *inappropriate* strategies to a new situation.

Transfer has several dimensions (Barnett & Ceci, 2002; Carpenter, 2012). You can transfer learning across subjects (math skills used in science problems), across physical contexts (learned in school, used on the job), across social contexts (learned alone, used with your family or team), across time periods (learned in college, used months or years later), across functions (learned for academics, used for hobbies and recreation), and across modalities (learned from watching the Home and Garden cable channel, used to discuss ideas for a patio with a landscape architect). So transfer can refer to many different examples of applying knowledge and skills beyond where, when, and how you learned them.

The Many Views of Transfer

Transfer has been a focus of research in educational psychology for over 100 years. After all, the productive use of knowledge, skills, and motivations across a lifetime is a fundamental goal of education (Goldstone & Day, 2012; Shaffer, 2010). Early work focused on specific transfer of skills and the general transfer of *mental discipline* gained from studying rigorous subjects such as Greek or mathematics. But in 1924, E. L. Thorndike demonstrated that no mental discipline benefit is derived from learning Greek. Learning Greek just helps you learn more Greek. So, thanks to Thorndike, you were not required to take Greek in high school.

More recently, researchers have distinguished between the automatic, direct use of skills such as reading or writing in everyday applications and the thoughtful transfer of knowledge and strategies to arrive at creative solutions to problems (Bereiter, 1995; Bransford & Schwartz, 1999). Automatic transfer probably benefits from practice in different situations, but thoughtful transfer requires more than practice. Michelene Chi and Kurt VanLehn (2012) describe thoughtful transfer as involving two processes—*initial learning* and *reusing or applying* what was learned. For thoughtful transfer to succeed, students must first actually learn the underlying principle or concept, not just the surface procedure or algorithm. So, essential to thoughtful transfer in the initial learning stage is *mindful abstraction*, which is the deliberate identification of a principle, main idea, strategy, or procedure that is not tied to one specific problem or situation but could apply to many. Such an abstraction becomes part of your metacognitive knowledge, available to guide future learning and problem solving. Table 9.3 on the next page summarizes the types of transfer.

Connect and Extend to PRAXIS II®

Transfer of Learning

Successful transfer of learning from the school to other contexts is evidence of superior instruction. What can teachers do to optimize transfer of knowledge and skills to the broader world?

Transfer Influence of previously learned material on new material; the productive (not reproductive) uses of cognitive tools and motivations.

TABLE 9.3 • Kinds of Transfer

	DIRECT APPLICATION	PREPARATION FOR FUTURE LEARNING
Definition	Automatic transfer of highly practiced skill	Conscious application of abstract knowledge to a new situation Productive use of cognitive tools and motivations
Key Conditions	Extensive practice Variety of settings and conditions Overlearning to automaticity	Mindful focus on abstracting a principle, main idea, or procedure that can be used in many situations Learning in powerful teaching–learning environments
Examples	Driving many different cars Finding your gate in an airport	Applying KWL or READS strategies Applying procedures from math in designing a page layout for the school newspaper

Teaching for Positive Transfer

Here is a great perspective on transfer from David Perkins and Gavriel Salomon (2012):

Schools are supposed to be stopovers in life, not ends in themselves. The information, skills, and understandings they offer are knowledge-to-go, not just to use on site. To be sure, often Monday's topics most conspicuously serve the Tuesday problem set, the Friday quiz, or the exam at the end of the year. However, in principle those topics are an investment toward thriving in family, civic, cultural, and professional lives. (p. 248)

Years of research and experience show that students will not always take advantage of knowledge-to-go. They may (seem to) learn new concepts, problem-solving procedures, and learning strategies Monday, but they may not use them for the year-end exam or even Friday unless prompted or guided. For example, studies of real-world mathematics show that people do not always apply math procedures learned in school to solve practical problems in their homes or at grocery stores (Lave, 1988; Lave & Wenger, 1991). This happens because learning is *situated*—tied to specific situations. Because knowledge is learned as a tool to solve particular problems, we may not realize that the knowledge is relevant when we encounter a problem that seems different, at least on the surface (Driscoll, 2005; Singley & Anderson, 1989). How can you make sure your students will use what they learn, even when situations change?

WHAT IS WORTH LEARNING? First, you must answer the question “What is worth learning?” The learning of basic skills such as reading, writing, computing, cooperating, and speaking will definitely transfer to other situations, because these skills are necessary for later work both in and out of school—writing job applications, reading novels, paying bills, working on a team, locating and evaluating health care services, among others. All later learning depends on positive transfer of these basic skills to new situations.

Teachers must also be aware of what the future is likely to hold for their students, both as a group and as individuals. What will society require of them as adults? As a child growing up in Texas in the 1950s and 1960s, I studied nothing about computers, even though my father was a computer systems analyst; yet now I spend hours at my Mac each day. Back then I learned to use a slide rule. Now, calculators and computers have made this skill obsolete. My mom encouraged me to take advanced math and physics instead of typing in high school. Those were great classes, but I struggle with typing

every day at my computer—who knew? Undoubtedly, changes as extreme and unpredictable as these await the students you will teach. For this reason, the general transfer of principles, attitudes, learning strategies, self-motivation, time management skills, and problem solving will be just as important for your students as the specific transfer of basic skills.

LESSONS FOR TEACHERS: SUPPORTING TRANSFER. For basic skills, greater transfer can also be ensured by **overlearning**, practicing a skill past the point of mastery. Many of the basic facts students learn in elementary school, such as the multiplication tables, are traditionally overlearned. Overlearning helps students develop automated basic skills as we saw in Chapter 8.

For higher-level transfer, students must first learn and understand. Students will be more likely to transfer knowledge to new situations if they have been actively involved in the learning process. Strategies include having students compare and contrast two examples, then identify the underlying principles; asking students to explain to themselves or each other the worked-out examples provided by the teacher; or identify for each step in a problem solution the underlying principle at work. Students also can learn an new concept, then explain it to peers, discuss it in small groups, or make videos to be used in peer learning (Chi & VanLehn, 2012; Hoogerheide, Loyens, & van Gog, 2014; Pai, Sears, & Maeda, 2015). Students should be encouraged to form abstractions that they will apply later, so they know transfer is an important goal. It also helps if students form deep connections between the new knowledge and their existing structures of knowledge as well as connections to their everyday experiences (Perkins & Salomon, 2012; Pugh & Phillips, 2011). Finally, one of the most powerful strategies for supporting transfer is retrieval practice through frequent testing and applying knowledge (Carpenter, 2012).

Positive transfer is encouraged when skills are practiced under authentic conditions, similar to those that will exist when the skills are needed later. Students can learn to write by corresponding with email pen pals in other countries. They can learn historical research methods by studying their own family history. Some of these applications should involve complex, ill-defined, unstructured problems, because many of the problems to be faced in later life, both in school and out, will not come to students complete with instructions.

One last kind of transfer is especially important for students—the transfer of the *learning strategies* we encountered earlier. Learning strategies are meant to be applied across a wide range of situations.

STAGES OF TRANSFER FOR STRATEGIES. Gary Phye (1992, 2001; Phye & Sanders, 1994) describes three stages in developing strategic transfer. In the *acquisition phase*, students should not only receive instruction about a strategy and how to use it but also rehearse the strategy and practice being aware of when and how they are using it. In the *retention phase*, more practice with feedback helps students hone their strategy use. In the *transfer phase*, students should be given new problems that they can solve with the same strategy, even though the problems appear different on the surface. To enhance motivation, teachers should point out to students how using the strategy will help them solve many problems and accomplish different tasks. These steps help build both procedural and self-regulatory knowledge—*how* to use the strategy as well as *when* and *why*.

Some students will learn productive strategies on their own, but all students can benefit from direct teaching, modeling, and practice of learning strategies and study skills. This is one important way to prepare all of your students for the future. Newly mastered concepts, principles, and strategies must be applied in a wide variety of situations and with many types of problems (Z. Chen & Mo, 2004). The *Guidelines: Family and Community Partnerships* on the next page give ideas for enlisting the support of families in encouraging transfer.

Overlearning Practicing a skill past the point of mastery.

GUIDELINES

FAMILY AND COMMUNITY PARTNERSHIPS

Promoting Transfer

Keep families informed about their child's curriculum so they can support learning.*Examples*

1. At the beginning of units or major projects, send a letter summarizing the key goals, a few of the major assignments, and some common problems students have in learning the material for that unit.
2. Ask parents for suggestions about how their child's interests could be connected to the curriculum topics.
3. Invite parents to school for an evening of "strategy learning." Have the students teach their family members one of the strategies they have learned in school.

Give families ideas for how they might encourage their children to practice, extend, or apply learning from school.*Examples*

1. To extend writing, ask parents to encourage their children to write letters or emails to companies or civic organizations asking for information or free products. Provide a shell letter form for structure and ideas, and include addresses of companies that provide free samples or information.
2. Ask family members to include their children in some projects that require measurement, halving or doubling recipes, or estimating costs.

3. Suggest that students work with grandparents to do a family memory book. Combine historical research and writing.

Show connections between learning in school and life outside school.*Examples*

1. Ask families to talk about and show how they use the skills their children are learning in their jobs, hobbies, or community involvement projects.
2. Ask family members to come to class to demonstrate how they use reading, writing, science, math, or other knowledge in their work.

Make families partners in practicing learning strategies.*Examples*

1. Focus on one learning strategy at a time. Ask families to simply remind their children to use a particular strategy with homework that week.
2. Develop a lending library of books, Website resources, and DVDs to teach families about learning strategies.
3. Give parents a copy of the *Guidelines: Becoming an Expert Student* on page 391, rewritten for your grade level.

MyLab Education [Self-Check 9.5](#)

BRINGING IT ALL TOGETHER: TEACHING FOR COMPLEX LEARNING AND ROBUST KNOWLEDGE

We began this chapter by talking about complex cognitive skills and higher-order learning. Then we went on to explore metacognition and learning strategies, problem solving and expertise, critical thinking and argumentation, and transfer of learning to new situations. Even though research in educational psychology has examined these topics for years, lately, some researchers have focused specifically on complex learning and teaching for robust knowledge (Richey & Nokes-Malach, 2015). In many ways this current focus brings together much of what we have learned in this chapter.

What Is Robust Knowledge?

The study of expertise points to three important characteristics of robust knowledge—it is deep, connected, and coherent. *Deep knowledge* is knowledge about underlying principles that allows experts to recognize the same principle-based features in seemingly different problems. For example, having robust knowledge in math enables students to see immediately that river current problems and airplane wind problems can be solved with the same underlying principles. *Connected knowledge* means many separate bits of information are linked—problem-solving steps are linked automatically within a problem, abstract principles are linked to specific features of a problem, concepts are linked

to appropriate procedures, and principles are connected across different disciplines and domains. *Coherent knowledge* is consistent and has no contradictions. Experts are much better than novices at detecting inconsistencies in knowledge (Richey & Nokes-Malach, 2015). As teachers, we want all our students to develop robust knowledge.

Recognizing and Assessing Robust Knowledge

How can we tell that someone has robust knowledge in a particular field? Table 9.4 contrasts novices with experts in the content and structure of their knowledge. As you can see, in terms of perceiving and representing the problem, novices focus on surface features, whereas experts focus on the structure and larger concepts underlying the problem. Experts can recall from their long-term memory many important details about the problem domain (such as math or physics or history), but novices rely mostly on what they can hold in their working memory, and they often get overwhelmed. They just don't have enough connected, relevant knowledge to bring to the workbench of working memory to solve the problem. In actually solving the problem, novices have to rely on general problem-solving strategies such as working backwards or trial-and-error. This takes a long time, is filled with errors and wrong turns, and often fails. Experts, on the other hand, quickly and accurately apply the appropriate domain-specific strategy for that particular problem type. Finally, because novices' knowledge is based on surface details of problems, they have no principles or conceptual knowledge to transfer to new situations, whereas the flexible, deep, connected, coherent knowledge of experts gives them abundant useful knowledge to transfer to new situations and problems.

Teaching for Robust Knowledge

What are some instructional strategies that help students move from novice to expert skill—that help them develop robust knowledge that is deep, connected, and coherent? In the next chapter we explore several teaching approaches such as inquiry and problem-based learning that target the construction of robust knowledge. Here, let's

TABLE 9.4 • What Robust Knowledge Looks Like in Action

This table contrasts the knowledge of novices and experts, based on how they perceive and represent problems, their working and long-term memory, problem-solving strategies, and ability to transfer knowledge to novel situations.

	NOVICES: LACKING ROBUST KNOWLEDGE	EXPERTS: WITH ROBUST KNOWLEDGE
Perception of Problem	Focuses on surface details like "It's a pulley problem"	Focuses on structure of underlying principles: "Newton's Law applies here."
Memory	Relies on working memory that quickly gets filled	Recalls many critical details, has vast store of connected knowledge in long-term memory
Problem Solving	Relies on general strategies; long, error-filled, often unsuccessful process	Quickly applies domain-relevant reasoning strategies to identify accurate solutions
Transfer	Has inflexible knowledge focused on surface details—does not have useful knowledge to transfer to novel situations	Has flexible knowledge—useful for applying to many situations

Source: Based on Richey, J. E., & Nokes-Malach, T. J. (2015). Comparing Four Instructional Techniques for Promoting Robust Knowledge. *Educational Psychology Review*, 27, p. 186.

examine four strategies that we have covered in this chapter and that can be incorporated into most teaching approaches: practice, worked examples, analogies, and self-explanation (Richey & Nokes-Malach, 2015).

PRACTICE. You have read about practice in several chapters of this book. Overlearning, or practicing even after you can do a skill or procedure, makes performance smooth, fast, and automatic—with little drain at all on working memory. Retrieval practice or testing is better than restudying for remembering information. Practice can be very effective in developing procedural knowledge of how to do things, but it is not that beneficial by itself in helping students learn to do analogous things—solve new problems; form abstract concepts and deep, principle-based understandings; or connect knowledge across situations. In fact, if your students are very practiced at one procedure in math or art or writing, they may try to apply it even when that procedure or skill is inappropriate, so developing robust knowledge takes more than practice.

WORKED EXAMPLES. Worked examples can support the development of robust knowledge by managing cognitive load so that students' working memory is not overwhelmed. This leaves enough working memory available to recognize and remember key features and deeper structures in the problem. Instead of trying to solve a problem by trial and error, students see the pathway and target their cognitive resources on learning. But worked examples and practice share some of the same obstacles to developing robust knowledge. Students can get better at doing the kind of problem in the examples, but not at doing different kinds of problems. One solution is to *interleave* (interweave or alternate) worked examples with practice problems and with other worked examples that have steps left out. This makes students think more deeply about what they are doing and why. But the best use of worked examples requires students to explain to themselves why each step in the example is necessary. This helps students develop connections between steps, basic principles, and procedures. Self-explanation is a powerful strategy, as you will soon see.

ANALOGIES. To use analogies, students map the similarities or shared features between two examples, cases, problems, time periods, works of art, and so on. Using analogies can support transfer as students apply what they know to recognize similar processes at work in seemingly different situations. The students are also building robust conceptual knowledge by linking key features in the problems to underlying principles. One problem, however, is that novices may identify analogies based on superficial similarities that have nothing to do with deep structure or underlying principles—for example, “both paintings are blue” instead of “both paintings are examples of cubism.” The careful selection of cases or problems plus some teacher guidance are important here.

SELF-EXPLANATIONS. To build robust knowledge, the big winner is self-explanation. Explaining each step in a worked example, drawing a model, explaining to a peer, providing evidence, telling why, justifying an answer—these self-explanations are better than detailed explanations by the teacher in building robust knowledge. You will learn in the next chapter that students who explain in a cooperative learning group learn more than students who receive explanations. Self-explanation encourages connections (why, what else, how, when...?) and coherence (does that make sense? Are there any contradictions in the explanation?).

▼ SUMMARY

Metacognition (pp. 368–371)

What is metacognition? Metacognition consists of knowledge and skills—*knowledge* about our own information-processing capabilities, the thinking and learning tasks we face, and the strategies needed. The three metacognitive *skills* used to regulate thinking and learning are planning, monitoring, and evaluating. *Planning* involves deciding how much time to give to a task, which strategies to use, how to start, and so on. *Monitoring* is the real-time awareness of “how I’m doing.” *Evaluating* involves making judgments about the processes and outcomes of thinking and learning and acting on those judgments.

What are some sources of individual differences in metacognition? Individual differences in metacognition may result from different paces of development (maturation) or biological differences among learners. For example, young students may not be able to understand a lesson’s purpose as well as older students.

How can teachers help students develop metacognitive knowledge and skills? With younger students, teachers can help students “look inside” to identify what they can do to read, write, or learn better. Systems such as KWL can help, if teachers demonstrate, explain, and model the strategy. For older students, teachers can build self-reflective questions into assignments and learning materials.

Learning Strategies (pp. 371–379)

What are learning strategies? Learning strategies are a special kind of procedural knowledge—*knowing how* to do something. A strategy for learning might include mnemonics to remember key terms, skimming to identify the organization, and then writing answers to possible essay questions. Use of strategies and tactics reflects metacognitive knowledge.

What key functions do learning strategies play? Learning strategies help students become cognitively engaged—focus attention on the relevant, important aspects of the material. Second, they encourage students to invest effort, make connections, elaborate, translate, organize, and reorganize to think and process deeply; the greater the practice and processing, the stronger the learning. Finally, strategies help students regulate and monitor their own learning—keep track of what is making sense and notice when a new approach is needed.

Describe some procedures for developing learning strategies. Expose students to a number of different strategies, not only general learning strategies but also very specific tactics, such as the graphic strategies. Teach conditional knowledge about when, where, and why to use various strategies. Develop motivation to use the strategies and tactics by showing students how their learning and performance can be improved. Provide direct instruction in content knowledge needed to use the strategies.

What is retrieval practice? This learning strategy is also called the *testing effect* or *active retrieval* and is more powerful than restudying. To benefit from this powerful strategy, students can practice recalling what they have learned by

listing key ideas, drawing concept maps, explaining to a friend, teaching another student, completing a KWL worksheet, taking a self-test, or anything else that requires active retrieval of the knowledge. Frequent tests and quizzes, even ungraded ones, are a form of retrieval practice.

When will students apply learning strategies? If they have appropriate strategies, students will apply them if they are faced with a task that requires good strategies, value doing well on that task, think the effort to apply the strategies will be worthwhile, and believe that they can succeed using the strategies. Also, to apply deep processing strategies, students must assume that knowledge is complex and takes time to learn and that learning requires their own active efforts.

Problem Solving (pp. 379–392)

What is problem solving? Problem solving is both general and domain specific. Also, problems can range from *well structured* to *ill structured*, depending on how clear-cut the goal is and how much structure is provided for solving the problem. General problem-solving strategies usually include the steps of *identifying* the problem, *setting goals*, *searching* for possible solutions, *anticipating* possible consequences, *acting*, and finally *looking back* to evaluate the outcome. Both general and specific problem solving are valuable and necessary.

How can worked examples help students develop powerful schemas for problem solving? Worked examples help students manage cognitive load (overload) and avoid inefficient trial-and-error learning. Worked examples chunk some of the steps, provide cues and feedback, focus attention on relevant information, and make fewer demands on memory, so the students can use cognitive resources to understand instead of searching randomly for solutions. To get the most benefit from worked examples, however, students have to actively engage—just “looking over” the examples is not enough. Here, self-explanation and using multiple learning channels (vision, touch, movement, hearing) support engagement.

Why is the representation stage of problem solving so important? To represent the problem accurately, you must understand both the whole problem and its discrete elements. Schema training may improve this ability. The problem-solving process follows entirely different paths, depending on what representation and goal are chosen. If your representation of the problem suggests an immediate solution, the task is done; the new problem is recognized as a “disguised” version of an old problem with a clear solution. But if there is no existing way of solving the problem or if the activated schema fails, then students must search for a solution. The application of algorithms and heuristics—such as means-ends analysis, working-backward, analogical thinking, and verbalization—may help students solve problems.

Describe factors that can interfere with problem solving. Factors that hinder problem solving include functional

fixedness or rigidity (response set). These disallow the flexibility needed to represent problems accurately and to have insight into solutions. Also, as we make decisions and judgments, we may overlook important information because we base judgments on what seems representative of a category (representativeness heuristic) or what is available in memory (availability heuristic), then pay attention only to information that confirms our choices (confirmation bias) so that we hold on to beliefs, even in the face of contradictory evidence (belief perseverance).

What are the differences between expert and novice knowledge in a given area? Expert problem solvers have a rich store of declarative, procedural, and conditional knowledge. They organize this knowledge around general principles or patterns that apply to large classes of problems. They work faster, remember relevant information, and monitor their progress better than novices. One consequence of developing expertise is that experts forget how difficult it was to learn something and how long it took. As a teacher, you will have to be sensitive about what it means for students to not understand.

Critical Thinking and Argumentation (pp. 392–396)

What is critical thinking? Critical thinking skills include defining and clarifying the problem, making judgments about the consistency and adequacy of the information related to a problem, and drawing conclusions. No matter what approach you use to develop critical thinking, it is important to follow up activities with additional practice. One lesson is not enough—overlearning will help students use critical thinking in their own lives.

What is argumentation? There are two styles of argumentation—*disputative* and *deliberative*. The heart of *disputative argumentation* is supporting your position with evidence and understanding and then refuting your opponent's claims and evidence. It is a competitive process where the goal is to convince an opponent to switch sides. The basic question is *who* is right. With *deliberative argumentation*, the goal is to collaborate in comparing, contrasting, and evaluating alternatives, then arrive at a constructive conclusion. The basic question is *which idea* is right. Argumentation skills are not natural. They take both time and instruction to learn. It is especially difficult for children and adolescents to pay attention to, understand, and refute an opponent's position with evidence (disputative argumentation). Deliberative argumentation also requires learning and practice.

Teaching for Transfer (pp. 397–400)

What is transfer? Transfer occurs when a rule, fact, or skill learned in one situation is applied in another situation; for example, applying rules of punctuation to write a job application letter. Transfer also involves applying to new problems the principles learned in other, often dissimilar situations.

What are some dimensions of transfer? Information can be transferred across a variety of contexts. Some examples include transfer from one subject to another, one physical location to another, or one function to another. These types of transfer make it possible to use skills developed in one area for many other tasks.

Distinguish between automatic and thoughtful transfer. Spontaneous application of well-learned knowledge and skills is automatic transfer. Thoughtful transfer involves *initial learning* and *reusing or applying* what was learned. Essential in the *initial learning* stage is mindful abstraction, which is the deliberate identification of a principle, main idea, strategy, or procedure that is not tied to one specific problem or situation but could apply to many. Learning environments should support active constructive learning, self-regulation, collaboration, and awareness of cognitive tools and motivational processes. In addition, students should deal with problems that have meaning in their lives. In addition, teachers can help students transfer learning strategies by teaching strategies directly, providing practice with feedback, and then expanding the application of the strategies to new and unfamiliar situations.

Teaching for Complex Learning and Robust Knowledge (pp. 400–402)

What is robust knowledge? Robust knowledge is deep, connected, and coherent. *Deep knowledge* is knowledge about underlying principles that allows experts to recognize the same principle-based features in seemingly different problems. *Connected knowledge* means many separate bits of information are linked—problem-solving steps are linked automatically within a problem, abstract principles are linked to specific features of a problem, concepts are linked to appropriate procedures, and principles are connected across different disciplines and domains. *Coherent knowledge* is consistent and has no contradictions.

How do you recognize robust knowledge? In terms of perceiving and representing the problem, novices focus on surface features, whereas experts focus on the structure and larger concepts underlying the problem. Experts can recall from their long-term memory many important details about the problem domain, but novices rely mostly on what they can hold in their working memory, and they often get overwhelmed. In actually solving the problem, novices have to rely on general problem-solving strategies that take a long time, are filled with errors, and often fail. Experts, on the other hand, quickly and accurately apply the appropriate domain-specific strategy for that particular problem type. Finally, because novices' knowledge is based on surface details of problems, they have no principles or conceptual knowledge to transfer to new situations, whereas the flexible, deep, connected, coherent knowledge of experts gives them abundant useful knowledge to transfer to new situations and problems.

How can teaching develop robust knowledge? Four strategies that we have covered in this chapter can be incorporated into most teaching approaches: practice, worked examples, analogies, and self-explanation. Each of these four strategies can be useful, but the big winner is self-explanation. Explaining each step in a worked example, drawing a model, explaining to a peer, providing evidence, telling why, justifying an answer—these self-explanations are better than detailed explanations by the teacher in building robust knowledge.

Verbalization (p. 387)
Working-backward strategy (p. 387)

▼ CONNECT AND EXTEND TO LICENSURE

MULTIPLE-CHOICE QUESTIONS

- Metacognition is broadly defined as the knowledge about our own thinking processes, that is, cognition about cognition. Which of the following cognitive abilities is not related to metacognition?
 - Declarative knowledge about your own academic progress
 - Procedural knowledge about the use of strategies
 - Self-regulatory knowledge to ensure the completion of the task
 - Belief perseverance even in the face of contradictory evidence
- Joshua is interested in teaching his students about dinosaurs. According to research on metacognitive development for younger students, which of the following sequential strategies is the most effective way of teaching the concept?
 - First, ask students, "What would you like to know about dinosaurs?" Then, "What do you already know about dinosaurs?" Finally, after the lesson, "Great! Please write down what you have learned."
 - First, ask students, "What do you already know about dinosaurs?" Then, "What would you like to know about dinosaurs?" Finally, after the lesson, "Great! Please write down what you have learned."
 - First, ask students, "What do you already know about dinosaurs?" Then, "Great! Please write down what you have learned!" Finally, after the lesson, "What do you still want to know about dinosaurs?"
 - First, ask students, "What would you like to know about dinosaurs?" Then, "What do you already know about dinosaurs?" Finally, "How can you find out what you want to know about dinosaurs?"

3. Teachers often neglect to teach their students about when, where, and why they should use various strategies. A strategy is more apt to be retained and appropriately used when educators directly teach which type of knowledge?
 - A. Declarative
 - B. Procedural
 - C. Self-regulatory
 - D. Rote
4. Ms. Tlali provided the following description of a person to her students: "Lewis is a man in his 50s. He likes to read, and he spends a lot of his time with books. He works in solitude and prefers cats over dogs." She then asked them to identify Lewis' occupation from among the following options: (1) history teacher, (2) Uber driver, (3) chef, and (4) construction worker. She noticed that most of her students identified Lewis as a (1) history teacher, while, in fact, he was more likely (by probability) to be one among options (2) to (4). What is this an example of?
 - A. Representativeness heuristics
 - B. Availability heuristics
 - C. Confirmation bias
 - D. Belief perseverance

CONSTRUCTED-RESPONSE QUESTIONS

Case

Sam walked in during Mr. Tan's office hours because he was not convinced by the topic discussed in the class earlier that day.

"Mr. Tan, earlier today, you told us that there are actually more words with *r* as the third letter than words that start with the letter *r*. How is that possible? Look, I can easily remember red, rectangle, radio, radar, and many others, but I have a hard time recalling words that have *r* as the third letter!"

"Sam, I understand that it might be difficult to believe, but if you go and look at the dictionary available in our library, you will discover that there are indeed more words that have *r* as the third letter as opposed to the first."

A few hours later, Sam returned to Mr. Tan's office.

"Mr. Tan, you are right! I wasn't even aware that I actually know more words with *r* as the third letter. After going through the dictionary, I now understand my own knowledge better!"

5. What is the key term that best describes Sam's argument before going to the library? Give reasons for your answer.
6. Which type of argumentation do you see at work in the discussion between Sam and his teacher? Discuss whether, and to what extent, you think such argumentation has impacted Sam's critical thinking.

▼ WHAT WOULD THEY DO?

TEACHERS' CASEBOOK: Uncritical Thinking

Here is how some practicing teachers would help students learn to critically evaluate the information they find on the Internet.

PAUL DRAGIN • ESL Teacher, Grades 9–12
Columbus East High School, Columbus, OH

This common problem does not have an easy fix. A few years ago, a student completed a research paper about 9/11, and the paper was filled with conspiracy theories that the student reported as fact. This dramatic example of undocumented, unsubstantiated research opened my eyes to the need to teach research methods far more explicitly to my students. Here is my general strategy to help ensure more quality research: After allowing the students to explore using Google and other common search engines to get some familiarity with their topic, I direct them to a reference database such as EBSCOhost or ProQuest, which, in our city, can be accessed with a library card via the public library Web site. Limiting the databases they can use reduces the likelihood that inaccurate and highly biased information makes its way into their reports. Demonstrating to them the difference between research-based, scholarly information and general information can go a long way in producing a product that demonstrates actual research.

SARA VINCENT • Special Education Teacher
Langley High School, McLean, VA

The Internet is a useful tool for students, but it is filled with a plethora of bad information. Luckily, the teacher in the described scenario can fix the problem before the students' submission of their final drafts. As an English teacher, I often encounter this problem but find that the majority of the students will comply if I set strict citation guidelines. After returning the first drafts to the students, I devote the next lesson to using credible sources rather than using less-reliable sources. I show examples of absurd claims from Internet Web sites. I also show the students how to find appropriate information. The students then exchange papers and complete a peer-editing lesson. In this lesson, students critique areas of their peers' drafts in which the sources were weak or nonexistent. To create strict citation guidelines, I tell my students that they are not allowed to use any Web site that ends in ".com." Instead, they only are allowed to use Web sites that end in ".edu" or ".gov," or they can use online databases such as JSTOR. Choosing to use an inappropriate site results in automatic failure on the assignment. If teachers use these strict guidelines, their students are highly likely to choose credible Web sites.

PAULA COLEMERE • Special Education Teacher—English, History

McClintock High School, Tempe, AZ

I usually teach my research unit after we have done persuasive reading and writing. Because I teach students how to evaluate information for bias during the persuasive unit, I know they have some prior knowledge before we tackle research. I show examples from scholarly journals, books, and general Web sites like Wikipedia. Then, as we discuss, I think aloud to model for students why I would or would not use a source. I typically do not allow my students to use any Web sources and keep them to the sites that are pre-approved in our library's database. If I were to allow a Web-based source, it would be limited to one. It is extremely helpful to students if you can show them sample research papers that are excellent, satisfactory, and poor. This way, they have an idea of what the finished product should look like. Another strategy would be to read a passage as a class and critically evaluate it together. Thinking critically is a skill that needs to be modeled and taught to kids. It is a mistake to assume they know how to do this on their own.

JESSICA N. MAHTABAN • Eighth-Grade Math Teacher

Woodrow Wilson Middle School, Clifton, NJ

The best way to show students how to evaluate information from Web sites is by modeling. I have a PowerPoint presentation that explains to students how to evaluate the authenticity of what they are reading on the Internet. Once the students become familiar with all the key points of how to evaluate Web sites, then I can show various Web sites on the Smart board, and as a class we can discuss and review the validity of the site.

We need to teach students how to articulate their thoughts by expanding on their ideas. Teachers can add "Why or why not?" or "explain" to the end of questions. If students are exposed to higher-level thinking questions and learn how to ask and answer these questions, then they can think more critically about school subjects.

JENNIFER PINCOSKI • Learning Resource Teacher: K–12

Lee County School District, Fort Myers, FL

Understanding that the Internet plays such a significant role in students' lives and that it does provide reliable information, the class needs to be taught how to appropriately use the Web for research. This involves teaching strategies on how to identify credible information, and providing ample opportunities for practice.

To understand that not all information on the Internet is accurate, students need to see real examples—examples that are relevant to them. This could be as simple as exposing them to several different sites that post conflicting information about the same topic and then asking them to define how they would decide which information to believe.

Once students recognize that they need to exercise discretion when retrieving information from the Internet, they can be taught HOW to do so. The teacher can provide a list of guiding questions that will help students critically evaluate their sources. The ultimate goal is for students to use the guiding questions independently and apply them across settings; however, in the beginning, students will require a much higher level

of support. An "I do, we do, you do" approach is probably the best way to assist students in the development and practice of these skills.

LAUREN ROLLINS • First-Grade Teacher

Boulevard Elementary School, Shaker Heights, OH

The Internet is a fantastic resource when it is used properly. Unfortunately, because anyone can post information on the Internet, it is not always reliable or factual. With respect to evaluating information found on the Internet, I encourage my students to visit multiple sites with multiple viewpoints so they can weigh the relative merits of each. In this way, they practice their critical thinking skills. Using examples of "factual" information found on Web sites that contradict clearly accepted facts will teach the students that they must evaluate information in the context of what they know to be true. This will help them to understand that multiple sources, not just the Internet, should be used. In addition, I devote some time to teaching my students how to properly cite sources from the Internet and other sources. This is an important skill and also a necessary one so that they will not be suspected of plagiarism.

LINDA SPARKS • First-Grade Teacher

John F. Kennedy School, Billerica, MA

Whenever I assign a new research project, I begin with a specific list of resource instructions. For example, I might state that I want two books, two magazine articles, and three Web sites. After the topic is picked, I have the students pull together their resources and come to me so that I can check them to make sure each student is headed in the right direction. It also gives me a better understanding of what they are researching and I can find out if they have any misconceptions about the project. I find I get better results this way, because the students know I am aware of what they are researching and have their lists of resources. (Even if they don't use all their sources, I want them to see what is available for them.) I also am more prepared to teach specific writing skills. The first skill I teach before I assign a project as they practice reading articles is how to take that information and transfer it into their own words. Limiting the number of quotes is a way to encourage higher-level thinking processes. Many times, when given the chance, students are more creative than the writers of the articles they read.

BARBARA PRESLEY • Transition/Work Study Coordinator—High School Level

BESTT Program (Baldwinsville Exceptional Student Training and Transition Program), C. W. Baker High School, Baldwinsville, NY

To me, discussion is key: whole-group discussion, small-group discussion, and one-to-one discussion, all the time being prepared to defend or criticize (with legitimate corroboration) topics raised. Students learn well from their mistakes as long as the correction is respectful and meaningful to them personally. They can't learn to think critically until someone questions their premises and they have to defend their position—as long as the discussions are conducted without malice. They are gaining experience in critical thinking through the process of criticism, both given and received.

chapter ten

CONSTRUCTIVISM AND DESIGNING LEARNING ENVIRONMENTS

WHAT WOULD YOU DO?

TEACHERS' CASEBOOK: Learning to Cooperate

You want to use cooperative learning with your middle school students. Many students have worked in groups, but few seem to have participated in true cooperative learning. When you surveyed the class members about their experiences, most rolled their eyes and groaned. You take it that their experiences have not been very positive. These students have a wide range of abilities, including some who are truly gifted and talented, several who are just learning English, and a few who are very shy; and then there are others who would take over and dominate every discussion if you let them. You believe that collaboration is a crucial 21st century skill for all students and that learning together can deepen understanding as students question, explain, and build on each other's thinking. No matter what, you hope the experience of learning together will build both your students' confidence and your sense of efficacy as a teacher, so you want authentic successes.

CRITICAL THINKING

- How would you begin to introduce cooperative learning to your students?
- What tasks will you choose to start?
- How will you establish groups?
- What will you watch and listen for to be sure the students are making the most of the experience?

PinkCat/Shutterstock

OVERVIEW AND OBJECTIVES

For the past three chapters, we have analyzed different aspects of learning. We considered behavioral, information processing, and cognitive science explanations of what and how people learn. We have examined complex cognitive processes such as metacognitive skills and problem solving. These explanations of learning focus on the individual and what is happening in his or her “head.” In this chapter, we expand our investigation of learning to include the social context of learning and the notion of constructivism. Constructivism is a broad perspective that calls attention to two critical aspects of learning: social and cultural factors. Sociocultural constructivist theories have roots in cognitive perspectives but have moved well beyond these early explanations. We will explore a number of teaching strategies and approaches that are consistent with constructivist perspectives—teacher facilitation, inquiry, problem-based learning, cooperative learning, cognitive apprenticeships, and reciprocal teaching. Finally, we will examine learning in this digital age, including the considerations about learning in technology-rich environments and the flipped classroom.

By the time you have completed this chapter, you should be able to:

- Objective 10.1 Explain different perspectives on constructivism as a theory of learning and teaching.
- Objective 10.2 Identify the common elements in most contemporary constructivist theories.
- Objective 10.3 Apply constructivist principles to classroom practice including using inquiry, problem-based learning, and cognitive apprenticeships.
- Objective 10.4 Appropriately incorporate collaboration and cooperative learning in your classes.
- Objective 10.5 Describe positive and negative influences of technology on the learning and development of children and adolescents.

OUTLINE

Teachers' Casebook—Learning to Cooperate: What Would You Do?

Overview and Objectives

Cognitive and Social Constructivism

- Constructivist Views of Learning
- How Is Knowledge Constructed?
- Knowledge: Situated or General?
- Common Elements of Constructivist Student-Centered Teaching

Designing Constructivist Learning Environments

- Assumptions to Guide the Design of Learning Environments
- Facilitating in a Constructivist Classroom
- Inquiry and Problem-Based Learning
- Cognitive Apprenticeships and Reciprocal Teaching

Collaboration and Cooperation

- Tasks for Cooperative Learning
- Setting Up Cooperative Groups
- Designs for Cooperation
- Reaching Every Student: Using Cooperative Learning Wisely
- Dilemmas of Constructivist Practice

Designing Learning Environments in a Digital World

- Technology and Learning
- Developmentally Appropriate Computer Activities for Young Children
- The Flipped Classroom

Summary and Key Terms

Teachers' Casebook—Learning to Cooperate: What Would They Do?

COGNITIVE AND SOCIAL CONSTRUCTIVISM

Consider this situation:

A young child who has never been to the hospital is in her bed in the pediatric wing. The nurse at the station down the hall calls over the intercom above the bed, "Hi Chelsea, how are you doing? Do you need anything?" The girl looks puzzled and does not answer. The nurse repeats the question with the same result. Finally, the nurse says emphatically, "Chelsea, are you there? Say something!" The little girl responds tentatively, "Hello, wall—I'm here."

Chelsea encountered a new situation—a talking wall. The wall is persistent. It sounds like a grown-up wall. She shouldn't talk to strangers, but she is not sure about walls. She uses what she knows and what the situation provides to construct meaning and to act.

Here is another example of constructing meaning. This time, Kate and her 9-year-old son Ethan co-construct understandings as they buy groceries:

Ethan: (running to get a shopping cart) Do we need the big one?

Kate: We might—better too big than not big enough. Here is our list—where do we go first?

Ethan: We need ice cream for the party! (Ethan heads toward frozen foods)

Kate: Whoa! What happened to the ice cream carton you left out on the kitchen counter?

Ethan: It melted and it wasn't out that long. I promise!

Kate: Right and we may be in this store a while, so let's start with things that won't melt while we are shopping—I usually buy produce first.

Ethan: What's "produce"?

Kate: Things that grow—fruits and vegetables "produced" by farmers.

Ethan: OK, the list says cucumbers. Here they are. Wait there are two kinds. Which do you want? The little ones say "local." What's local?

Kate: Local means from around here—close to us, close to our "location."

Ethan: Is local better?

Kate: Maybe. I like to support our local farmers. Where are the small cucumbers from—look at the tiny print on the label.

Ethan: Virginia—is that close to us?

Kate: Not really—it is about a 6-hour drive from here. . . .

Look at the knowledge being co-constructed about planning ahead, vocabulary, problem solving, and even geography. Constructivist perspectives of learning focus on how people make meaning, both on their own like Chelsea and in interaction with others like Ethan.

Constructivism/ constructivist approach

View that emphasizes the active role of the learner in building understanding and making sense of information.

Constructivist Views of Learning

Constructivism is a broad and much debated term. Actually, constructivism is more a *philosophy* about knowledge than a scientific theory of learning. Various constructivist perspectives are grounded in the research of Piaget, Vygotsky, the Gestalt psychologists, and the work of Bartlett, Bruner, and Rogoff; in addition, the philosophy of John Dewey

and the work in anthropology of Jean Lave are also among the many intellectual origins of this philosophy. But even though many psychologists and educators use the term *constructivism*, they often mean very different things (J. Martin, 2006; McCaslin & Hickey, 2001; Phillips, 1997). Although there is no single constructivist theory, most constructivist perspectives do agree on two central ideas:

Central Idea 1: Learners are active in constructing their own understanding—they create knowledge by going beyond the information they are given (Chi & Wylie, 2014).

Central Idea 2: Social interactions are important in this knowledge construction process (Bruning, Schraw, & Norby, 2011; Schunk, 2016).

One way to organize constructivist views is to describe two forms of constructivism that match these central ideas: cognitive and social construction (Palincsar, 1998; Phillips, 1997). *Cognitive constructivists* focus on how individuals use information, resources, and even help from others to build understanding—see Central Idea 1. In contrast, *social constructivists* view learning as increasing our abilities to participate with others in activities that are meaningful in the culture—see Central Idea 2 (Dohn, 2016; Windschitl, 2002). Let's look a bit closer at each type of constructivism.

COGNITIVE CONSTRUCTIVISM. Many psychological theories include some kind of constructivism because these theories embrace the idea that individuals construct their own cognitive structures as they make sense of their experiences (Palincsar, 1998). Because they study individual knowledge, beliefs, self-concept, or identity, they are sometimes called *individual constructivists* or *psychological constructivists*; they all focus on the inner psychological life of people. When Chelsea talked to the wall in the previous section, she was making meaning using her own individual knowledge and beliefs about how to respond when someone (or something) talks to you (Piaget, 1971; Windschitl, 2002). When children observe that most plants need soil to grow and then conclude that plants “eat dirt,” they are using what they know about how eating supports life to make sense of plant growth (M. C. Linn & Eylon, 2006).

Using these standards, the most recent *information processing* theories are constructivist because they are concerned with how individuals construct internal representations (propositions, images, concepts, schemas) that can be remembered and retrieved (Mayer, 1996; Schunk, 2016). Some psychologists, however, believe that information processing is “trivial” or “weak” constructivism because the individual's only constructive contribution is to build accurate internal representations of the outside world, not to construct a unique and individual understanding (Derry, 1992; Garrison, 1995; H. H. Marshall, 1996; Windschitl, 2002).

In contrast, Piaget's psychological (cognitive) constructivist perspective is less concerned with “correct” representations and more interested in meaning as constructed by the individual. Piaget's special focus was on logic and the construction of universal knowledge such as *conservation* or *reversibility* (P. H. Miller, 2016). Such knowledge comes from reflecting on and coordinating our own cognitions or thoughts, not from copying external reality. Piaget saw the social environment as an important factor in development, but did not believe that social interaction was the main mechanism for changing thinking.

At the extreme end of individual constructivism is the notion of **radical constructivism**. This perspective holds that each of us constructs meaning (knowledge) from our own experiences as we try to explain to ourselves what we perceive, but we have no way of understanding or “knowing” the knowledge constructed by others or even whether our knowledge is “correct.” Learning for radical constructivists consists of replacing one construction with another that better explains the person's current perceptions of reality (Hennessey et al., 2012). A difficulty with this position is that, when pushed to the extreme of relativism, all knowledge and all beliefs are equal because they are all valid individual perceptions.

There are problems with this thinking for educators. First, teachers have a professional responsibility to emphasize some values, such as honesty or justice, over others,

MyLab Education
Video Example 10.1

The young students in this science class are investigating earthworms. In pairs, they are finding answers to their questions and constructing their own knowledge with the teacher's guidance. Notice the active role of the students in building understanding, and making sense of information about earthworms.

Radical constructivism Knowledge is assumed to be the individual's construction; it cannot be judged right or wrong.

such as deception and bigotry. All perceptions and beliefs are not equal. Second, there are right answers in many fields such as mathematics, and students will have trouble learning if they hold on to personal misconceptions and naïve constructions. As teachers, we ask students to work hard to learn. If learning cannot advance understanding because all understandings are equally good, then, as David Moshman (1997) noted, “we might just as well let students continue to believe whatever they believe” (p. 230). Also, it appears that some knowledge, such as counting and one-to-one correspondence, is not constructed, but innate. Knowing one-to-one correspondence is part of being human (Geary, 1995; Schunk, 2016).

SOCIAL CONSTRUCTIVISM. In cognitive constructivism, learning means individually possessing knowledge (Central Idea 1), but in social constructivism, learning means belonging to a group and participating with that group in the social construction of knowledge (Central Idea 2) (Dohn, 2016; Mason, 2007). Vygotsky emphasized the second idea, that social interaction, cultural tools, and activity shape individual development and learning, just as Ethan’s interactions and activities in the grocery store with his mother shaped his learning about anticipating possible consequences (running out of space in the shopping cart and melted ice cream), the meaning of “produce” and “local,” and geography—where is Virginia? (J. Martin, 2006). By participating in a broad range of activities with others, learners *appropriate* the outcomes produced by working together; these outcomes could include both new strategies and knowledge. **Appropriating** means being able to reason, act, and participate using cultural tools—for example, using conceptual tools such as “force” and “acceleration” to reason in physics (Mason, 2007).

Because Vygotsky’s theory relies heavily on social interactions and the cultural context to explain learning, most psychologists classify him as a social constructivist (Palincsar, 1998; Prawat, 1996). However, some theorists categorize him as a cognitive constructivist because he was primarily interested in development within the individual (Moshman, 1997; Phillips, 1997). In a sense, Vygotsky was both. One advantage of his theory of learning is that it gives us a way to consider both the cognitive and the social: He bridges both camps. For example, Vygotsky’s concept of the *zone of proximal development*—the area in which a child can solve a problem with the help (scaffolding) of an adult or more able peer—has been called a place where culture and cognition create each other (M. Cole, 1985). Culture creates cognition when the adult uses tools and practices from the culture (language, maps, computers, looms, or music) to steer the child toward goals the culture values (reading, writing, weaving, dance). Cognition creates culture as the adult and child or several adults together generate new practices and problem solutions to add to the cultural group’s repertoire (Serpell, 1993). So people are both products and producers of their societies and cultures (Bandura, 2001). One way of integrating cognitive and social constructivism is to think of knowledge as both *individually constructed* and *socially mediated* (Windschitl, 2002).

These two different perspectives on constructivism raise some general questions, create some tensions, and suggest different answers, as you will see next.

How Is Knowledge Constructed?

One tension is based on *how* knowledge is constructed. There are three explanations, shown in Table 10.1, based on Bruning, Schraw, and Norby (2011), Moshman (1982), and Schunk (2016).

Knowledge: Situated or General?

A second question that cuts across many constructivist perspectives is whether knowledge is internal, general, and transferable, or bound to the time and place in which it is constructed. Psychologists who emphasize the social construction of knowledge and situated learning affirm Vygotsky’s notion that learning is inherently social and embedded in a particular cultural setting (Cobb & Bowers, 1999; Dohn, 2016; Schoor, Narciss, & Körndle, 2015). What is true in one time and place—such as the “fact” before Columbus’s

Appropriating Being able to internalize or take for yourself knowledge and skills developed in interaction with others or with cultural tools.

TABLE 10.1 • How Knowledge Is Constructed

TYPE	ASSUMPTIONS ABOUT LEARNING AND KNOWLEDGE	EXAMPLE THEORIES
External Direction	Knowledge is acquired by constructing a representation of the outside world. Direct teaching, feedback, and explanation affect learning. Knowledge is accurate to the extent that it reflects the “way things really are” in the outside world.	Information processing
Internal Direction	Knowledge is constructed by transforming, organizing, and reorganizing previous knowledge. Knowledge is not a mirror of the external world, even though experience influences thinking and thinking influences knowledge. Exploration and discovery are more important than teaching.	Piaget
Both External and Internal Direction	Knowledge is constructed based on social interactions and experience. Knowledge reflects the outside world as filtered through and influenced by culture, language, beliefs, interactions with others, direct teaching, and modeling. Guided discovery, teaching, models, and coaching as well as the individual’s prior knowledge, beliefs, and thinking affect learning.	Vygotsky

time that the earth was flat—becomes false in another time and place. Particular ideas may be useful within a specific **community of practice**, such as fifteenth-century navigation, but useless outside that community. What counts as new knowledge is determined in part by how well the new idea fits with current accepted practice. Over time, the current practice may be questioned and even overthrown, but until such major shifts occur, current practice will shape what is considered valuable, and even what is considered knowledge.

Situated learning emphasizes that learning in the real world is not like studying in school. It is more like an apprenticeship where novices, with the support of an expert guide and model, take on more and more responsibility until they can function independently. Proponents of this view believe situated learning explains learning in factories, around the dinner table, in high school halls, in street gangs, in the business office, and on the playground.

Situated learning is often described as “enculturation,” or forming an identity within a particular community by adopting its norms, behaviors, skills, beliefs, language, and attitudes. The community might be mathematicians or gang members or writers or students in your eighth-grade class or soccer players—any group that has particular ways of thinking and acting. Knowledge is viewed not as individual cognitive structures, but rather as a creation of the community over time. The practices of the community—the ways of interacting and getting things done, as well as the identities and tools the community has created—constitute the knowledge of that community. Learning means becoming more able to participate in those practices, take on those identities, and use the tools (Dohn, 2016; Greeno, Collins, & Resnick, 1996; Mason, 2007).

At the most basic level, “situated learning emphasizes the idea that much of what is learned is specific to the situation in which it is learned” (J. R. Anderson, Reder, & Simon, 1996, p. 5). Thus, some would argue, learning to do calculations in school may help students do more school calculations, because the skills can be applied only in the context in which they were learned—namely, school (Lave, 1997; Lave & Wenger, 1991). But it also appears that knowledge and skills can be applied across contexts that were not part of the initial learning situation, as when you use your ability to read and

Community of practice

Social situation or context in which ideas are judged useful or true.

Situated learning The idea that skills and knowledge are tied to the situation in which they were learned and that they are difficult to apply in new settings.

calculate to do your income taxes, even though income tax forms were not part of your high school curriculum (Schunk, 2016).

Learning that is situated in school does not have to be isolated or irrelevant (Bereiter, 1997). As you saw in Chapter 9, a major question in educational psychology—and education in general—concerns the transfer of knowledge from one situation to another. How can you encourage this transfer from one situation to another? Help is on the way in the next section.

MyLab Education Video Example 10.2

In Mr. Fireng's middle school science class, the students engage in peer teaching. Students work together in groups to develop expertise about one concept in their science unit, plan a lesson and activities around their concept, and teach that concept to their peers. Observe the student-centered focus of Mr. Fireng's approach.

Connect and Extend to PRAXIS II®

Student-Centered Learning (II, A3)

Many of the major initiatives to reform content-area curricula (e.g., science, mathematics) emphasize student-centered/constructivist approaches to learning. Describe the major principles of these approaches, and explain how they differ from teacher-centered approaches.

Complex learning environments Problems and learning situations that mimic the ill-structured nature of real life.

Common Elements of Constructivist Student-Centered Teaching

STOP & THINK What makes a lesson student centered? List the characteristics and features that put the student in the center of learning. •

We have looked at some areas of disagreement among the constructivist perspectives, but what about areas of agreement? All constructivist perspectives assume that knowing develops as learners, like Chelsea and Ethan, try to make sense of their experiences. “Learners, therefore, are not empty vessels waiting to be filled, but rather active organisms seeking meaning” (Driscoll, 2005, p. 487). Humans construct mental models or schemas and continue to revise them to make better sense of their experiences. We are knowledge inventors, not copy machines or filing cabinets. Our constructions do not necessarily resemble external reality; rather, they are our unique interpretations, like Chelsea's friendly, persistent wall. This doesn't mean that all constructions are equally useful or viable. Learners test their understandings against experience and the understandings of other people—they negotiate and co-construct meanings like Ethan did with his mother.

Constructivists share similar goals for learning. They emphasize knowledge *in use* rather than the *storing* of inert facts, concepts, and skills. Learning goals include developing abilities to find and solve ill-structured problems, critical thinking, inquiry, self-determination, and openness to multiple perspectives (Driscoll, 2005). Even though there is no single constructivist theory, many constructivist approaches recommend five conditions for learning:

1. Embed learning in complex, realistic, and relevant learning environments.
2. Provide for social negotiation and shared responsibility as a part of learning.
3. Support multiple perspectives, and use multiple representations of content.
4. Nurture self-awareness and an understanding that knowledge is constructed.
5. Encourage ownership in learning. (Driscoll, 2005; H. H. Marshall, 1992)

Before we discuss particular teaching approaches, let's look more closely at these dimensions of constructivist teaching.

COMPLEX LEARNING ENVIRONMENTS AND AUTHENTIC TASKS. Constructivists believe that students should not be given stripped-down, simplified problems and basic skills drills, but instead should encounter **complex learning environments** that deal with “fuzzy,” ill-structured problems. The world beyond school presents few simple problems or step-by-step directions, so schools should be sure that every student has experience solving complex problems. Complex problems are not just difficult ones; rather, they have many parts. There are multiple, interacting elements in complex problems and multiple possible solutions. There is no one right way to reach a conclusion, and each solution may bring a new set of problems.

These complex problems should be embedded in authentic tasks and activities, the kinds of situations that students would face as they apply what they are learning in the real world. Students may need support (*scaffolding*) as they work on these complex problems, with teachers helping them find resources, keeping track of their progress, breaking larger problems down into smaller ones, and so on. This aspect of constructivist

approaches is consistent with situated learning in emphasizing learning in situations where the knowledge will be applied.

SOCIAL NEGOTIATION. Many constructivists share Vygotsky's belief that higher mental processes develop through **social negotiation** and interaction, so collaboration in learning is valued. A major goal of teaching is to develop students' *critical thinking* and *argumentation*—the abilities to establish and defend their own positions while respecting the positions of others and working together to negotiate or co-construct meaning. To accomplish this exchange, students must talk and listen to each other. It is a challenge for children in cultures that are individualistic and competitive, such as the United States, to adopt what has been called an **intersubjective attitude**—a commitment to build shared meaning by finding common ground and exchanging interpretations.

MULTIPLE PERSPECTIVES AND REPRESENTATIONS OF CONTENT. When students encounter only one model, one analogy, one way of understanding complex content, they often oversimplify as they try to apply that one approach to every situation. I saw this happen in my educational psychology class when six students were presenting an example of guided discovery learning. The students' presentation was a near copy of a guided discovery demonstration I had given earlier in the semester, but with some major misconceptions. My students knew only one way to represent discovery learning. Resources for the class should have provided **multiple representations of content** using different analogies, examples, and metaphors. This idea is consistent with Jerome Bruner's (1966) **spiral curriculum**, a structure for teaching that introduces the fundamental structure of all subjects—the “big ideas”—early in the school years, then revisits the subjects in more and more complex forms over time. Another example, the use of manipulatives in mathematics, allows students different ways to represent the quantities and processes in mathematics (Carbonneau, Marley, & Selig, 2012).

UNDERSTANDING THE KNOWLEDGE CONSTRUCTION PROCESS. Constructivist approaches emphasize making students aware of their own role in constructing knowledge. The assumptions we make, our beliefs, and our experiences shape what each of us comes to “know” about the world. Different assumptions and different experiences lead to different knowledge, as we saw in Chapter 6 when we explored the role of cultural differences in shaping knowledge. If students are aware of the influences that shape their thinking, they will be more able to choose, develop, and defend positions in a self-critical way while respecting the positions of others.

STUDENT OWNERSHIP OF LEARNING. “While there are several interpretations of what [constructivist] theory means, most agree that it involves a dramatic change in the focus of teaching, putting the students' own efforts to understand at the center of the educational enterprise” (Prawat, 1992, p. 357). Student ownership does not mean that the teacher abandons responsibility for instruction. Because the design of teaching is a central issue in this book, we will spend the rest of this chapter discussing examples of *ownership of learning* and *student-centered instruction*.

MyLab Education **Self-Check 10.1**

DESIGNING CONSTRUCTIVIST LEARNING ENVIRONMENTS

Designing learning environments means translating our knowledge about learning and motivation into activities, assignments, assessments, and other resources for instruction (Belland, Kim, & Hannafin, 2013). Educational psychologists are not the only people who study how to design learning environments. In fact, an interdisciplinary field often

Social negotiation Aspect of learning process that relies on collaboration with others and respect for different perspectives.

Intersubjective attitude A commitment to build shared meaning with others by finding common ground and exchanging interpretations.

Multiple representations of content Considering problems using various analogies, examples, and metaphors.

Spiral curriculum Bruner's design for teaching that introduces the fundamental structure of all subjects early in the school years, then revisits the subjects in more and more complex forms over time.

called the **learning sciences** encompasses research in psychology, education, computer science, philosophy, sociology, anthropology, neuroscience, and other fields that study learning and learning environments. No matter what their focus is, all knowledge workers are interested in how deep robust knowledge in subjects like science, mathematics, and literacy is actually acquired.

Assumptions to Guide the Design of Learning Environments

Here are some basic assumptions to guide our consideration of how to design powerful learning environments (Sawyer, 2006):

- *Experts have deep conceptual knowledge.* Experts know many facts and procedures, but just learning facts and procedures will not make you an expert. Experts have deep conceptual understanding that allows them to put their knowledge into action; they can apply and modify their knowledge to fit each situation.
- *Learning comes from the learner.* Better instruction alone will not transfer deep understandings from teachers to students. Learning is more than receiving and processing information transmitted by teachers or texts. Rather, students must actively participate in their own personal construction of knowledge. Again, we are knowledge inventors, not copy machines (de Kock, Slegers, & Voeten, 2004).
- *Schools must create effective learning environments.* It is the job of the school to create environments where students are active in constructing their own deep understandings so they can reason about real-world problems and transfer their learning from school to their lives beyond the school walls.
- *Prior knowledge and beliefs are key.* Students come into our classrooms filled with knowledge and beliefs about how the world works. Some of these preconceptions are right, some are part right, and some are wrong. If teaching does not begin with what the students “know,” then the students will learn what it takes to pass the test, but their knowledge and beliefs about the world will not change (Hennessey, Higley, & Chesnut, 2012).
- *Reflection is necessary to develop deep conceptual knowledge.* Students need to express and perform the knowledge they are developing through writing, conversations, drawings, projects, skits, portfolios, reports, and so on. But the performance is not enough. To develop deep conceptual knowledge, students need to reflect—thoughtfully analyze their own work and progress.

Keith Sawyer (2006) contrasts learning environments designed based on these assumptions with traditional classroom practices that have dominated schooling in many countries for decades. Look at Table 10.2 to see the differences.

Even though, as you can see again in Table 10.2, the student is at the center of constructivist perspectives of learning, this does not mean that teachers are irrelevant or obsolete. In constructivist classrooms, teachers are facilitators and learning environment designers.

Facilitating in a Constructivist Classroom

Mark Windschitl (2002) suggests the following ways that teachers can encourage meaningful learning. To facilitate learning, teachers:

- Elicit students’ ideas and experiences in relation to key topics, then fashion learning situations that help students elaborate on or restructure their current knowledge.
- Provide students with a variety of information resources as well as the tools (technological and conceptual) necessary to mediate learning.
- Make their own thinking processes explicit to learners and encourage students to do the same through dialogue, writing, drawings, or other representations.
- Encourage students’ reflective and autonomous thinking in conjunction with the conditions listed above.
- Employ a variety of assessment strategies to understand how students’ ideas are evolving and then give feedback on the processes as well as the products of their thinking. (p. 137).

Learning sciences An interdisciplinary science of learning, based on research in psychology, education, computer science, philosophy, sociology, anthropology, neuroscience, and other fields that study learning.

TABLE 10.2 • How Deep Learning Contrasts with Learning in Traditional Classrooms

LEARNING IN TRADITIONAL CLASSROOMS	BUT FINDINGS FROM COGNITIVE SCIENCE SHOW OTHER REQUIREMENTS FOR DEEP LEARNING
Class material is not related to what students already know. Example: Teacher says, "Igneous rocks are. . ."	Learners relate new understandings to what they already know and believe. Example: Teacher says, "Have any of you seen granite counter tops on TV home shows or maybe you have one in your house? What do they look like . . .?"
Class material presented and learned as disconnected bits of knowledge. "The definition of metamorphic rocks is. . ."	Learners integrate and interconnect their knowledge in expanding conceptual systems. "We already have learned about two kinds of rocks. We also learned last week about how the earth has changed over the centuries, with some ocean floors becoming land areas. Today we will learn about how marble and diamonds. . ."
Lessons involve memorizing facts and doing procedures without understanding how or why. "To divide fractions, invert and multiply. . ."	Learners search for patterns and recognize or invent underlying principles. "Remind me what it means to divide. . . Ok, so $3/4$ divided by $1/2$ means how many sets of what are in . . .?"
Learners have trouble understanding ideas that are not straight from the textbook or explained in the same way. "What does your textbook say about . . .?"	Learners evaluate new ideas, even if not in the text, and integrate them into their thinking. "On TV yesterday there was a story about a new drug that is effective in curing one out of 8 cases of. . . What is the probability of a cure?"
Authorities and experts are the source of unchanging and accurate facts and procedures. "Scientists agree. . ."	Learners understand that knowledge is socially constructed by people, so ideas require critical examination. "Here are brief summaries of two positions about climate change. Let's think about how you would determine which position is more supported by evidence . . .?"
Learners simply memorize everything instead of thinking about the purpose of learning and the best strategies for that purpose. "This will be on the test."	Learners think about why they are learning, monitor their understanding, and reflect on their own learning processes. "How could you use this concept in your own life? How can you tell if you are understanding it?"

Source: Based on Sawyer, R. K. (2006). The New Science of Learning. In R. K. Sawyer (Ed.), *The Cambridge Handbook of the Learning Sciences* (p. 4). New York: Cambridge University Press.

SCAFFOLDING. Constructivist approaches include **scaffolding** to support students' developing expertise. One implication of Vygotsky's theory of cognitive development is that deep understanding requires that students grapple with problems in their zone of proximal development, where they construct knowledge with support; students need scaffolding in order to work in that zone. Here is a good definition of scaffolding that emphasizes its dynamic interactive nature as well as the knowledge that both teacher and student bring to the learning situation—both are experts on something: "Scaffolding is a powerful conception of teaching and learning in which teachers and students create meaningful connections between teachers' cultural knowledge and the everyday experience and knowledge of the student" (McCaslin & Hickey, 2001, p. 137). Look back at the grocery store conversation between Ethan and his mother. Notice how the mother used the melted ice cream on the kitchen counter—connecting to Ethan's experience and knowledge—to scaffold Ethan's understanding.

Scaffolding Teachers and students make meaningful connections between what the teacher knows and what the students know and need in order to help the students learn more.

MyLab Education Video Example 10.3

In Mr. Fireng's middle school science class, he provides scaffolding as needed. Observe how he prompts a student who needs a little help to answer the warm-up questions about ticks. Notice how he encourages the student from China when an English word becomes a barrier to her learning. What is the role of social interaction in the learning that is taking place in this classroom?

The original definition of scaffolding (Wood et al., 1976) included both *motivational* and *cognitive* support—helping students stay engaged and interested while also helping them move toward deeper learning (Belland, 2014). *Motivational scaffolding* includes recruiting the students' interests and enthusiasm to engage with the learning activity, maintaining the students' attention and redirecting when the students stray off task, and helping students control their emotions if learning gets frustrating. These motivational supports are important for all students, but especially for students with learning challenges (Radford et al., 2015).

Cognitive scaffolding has three characteristics (Radford, Bosanquent, Webster, & Blatchford, 2015; van de Pol, Volman, & Beishuizen, 2010):

1. *Contingency Support*: The teacher is constantly adjusting, differentiating, and tailoring responses to the students.
2. *Fading*: The teacher gradually withdraws support as the students' understanding and skills deepen.
3. *Transferring Responsibility*: Students assume more and more responsibility for their own learning.

There are a number of ways teachers can provide *contingency support*, including prompting, modeling, and reminders. For example, to study the role of teacher support in the growth of student relational thinking, Tzu-Jung Lin and her colleagues analyzed over 35,000 exchanges during the problem-based discussions in small groups of fourth graders. The researchers found that teachers' prompts for relational thinking—encouraging logical reasoning, use of analogies, counterargument, alternative hypotheses, and elaborated clarifications—led to better student relational thinking. Once the teacher coached one student to think more deeply, the relational thinking spread to other members of the group—they scaffolded each other. Other effective teacher supports included praising students for using cognitive strategies and prompting the group to stay on task, not interrupt each other, take turns, and be sure everyone contributed (Lin et al., 2015).

Fading support can involve moving from concrete to abstract problems. This strategy is in keeping with the U.S. Institute of Education Science's recommendations that encourage teachers to "Connect and integrate abstract representations of a concept with concrete representations of the same concept" (Pashler et al., 2007, p. 13). One example of the importance of fading comes from three studies of mathematics learning in elementary school (Fyfe, McNeil, & Borjas, 2015). The researchers tested four ways of teaching math to first through third graders: problems presented using concrete material only, problems presented using abstract (numbers only) instruction, problems presented that faded from concrete to abstract, and problems that started abstract and became more concrete. In the three different studies, concrete fading to abstract instruction, like that shown in Figure 10.1, was more effective, even for students with greater prior knowledge in math.

To *transfer responsibility* and support growing expertise, scaffolds should be designed so the students make choices as they learn, consider the consequences of different options, make decisions about strategies, and select paths of action. If students are following this approach, they will be able to assume more and more responsibility for their own learning, so fading will be more successful (Belland, 2011). These kinds of scaffolds also help students to become "self-scaffolding" (Radford et al., 2015).

ADVANCE ORGANIZERS AS SCAFFOLDING. One way to scaffold both learning and motivation is to begin a lesson or activity with an **advance organizer** (Melrose, 2013). This is the provision of introductory material broad enough to encompass all the information that will follow. The organizers can serve three purposes: They direct your attention to what is important in the upcoming material, they highlight relationships among ideas that will be presented, and they remind you of relevant information you already have.

Advance organizers fall into two categories, comparative and expository (Mayer, 1984). *Comparative organizers* activate (bring into working memory) already existing schemas. They remind you of what you already know but may not realize is relevant to

Connect and Extend to PRAXIS II®

Advance Organizers (II, A3)

The advance organizer is an important element in many teacher-centered/expository approaches to instruction. Be able to explain the role of the advance organizer in these approaches, and identify the basic types of organizers.

Advance organizer

FIGURE 10.1

FADING INSTRUCTION FROM CONCRETE MATERIALS TO ABSTRACT PROBLEMS

Elementary age students learned some basic math concepts by beginning with concrete materials—how do you have the give the same number of stickers to the monkey and to the frog?, then moving to a work sheet asking the same question, and finally working with an abstract problem using numbers only.

Source: From Fyfe, E. R., McNeil, N. M., & Borjas, S. (2015). Benefits of "Concreteness Fading" for Children's Mathematics Understanding. *Learning and Instruction*, 35, p. 107.

the new topic being discussed. A comparative advance organizer for a history lesson on revolutions might be a statement that contrasts military uprisings with the physical and social changes involved in the Industrial Revolution; you could also compare the common aspects of the French, English, Mexican, Russian, Iranian, Egyptian, and American revolutions (Salomon & Perkins, 1989).

In contrast, *expository organizers* provide new knowledge that students will need in order to understand the upcoming information. In an English class, you might begin a large thematic unit on rites of passage in literature with a very broad statement of the theme and a brief analysis about why it has been so central in literature—something like, "A central character coming of age must learn to know himself or herself, often makes some kind of journey of self-discovery, and must decide what in the society is to be accepted and what should be rejected." Such an organizer might precede reading novels such as *The Adventures of Huckleberry Finn*.

The general conclusion of research on advance organizers is that they do scaffold student learning, especially when the material to be learned is quite unfamiliar, complex, or difficult—as long as two conditions are met (Langan-Fox, Waycott, & Albert, 2000; Morin & Miller, 1998). First, to be effective, the students must understand the organizer. This was demonstrated dramatically in a classic study by Dinnel and Glover (1985). They found that instructing students to paraphrase an advance organizer—which, of course, requires them to understand its meaning—increased the effectiveness of the organizer. Second, the organizer must really be an organizer: It must indicate relations among the basic concepts and terms that will be used in the upcoming lesson. Concrete models, diagrams, concept maps, charts, timelines, or analogies seem to be especially good organizers (D. H. Robinson, 1998; D. H. Robinson & Kiewra, 1995).

FACILITATING THROUGH ASKING AND ANSWERING DEEP QUESTIONS. Studies with students from fourth grade through college in subjects as diverse as science, mathematics, history, and literature show that teachers can facilitate learning by training students to ask and answer deep questions when they read, listen to a lecture, or participate in class discussions. To be effective, you first must be sure that all your students have the necessary basic facts and knowledge to think deeply about. Then you can identify questions that prompt students to reason about underlying principles and big ideas in the content, make reasoned arguments, and provide evidence (Pashler et al., 2007). It is not easy or natural to ask and answer deep questions. Students have to be supported as they learn these skills. The *Guidelines for Facilitating Deep Questioning* on the next page, taken from Pashler et al. (2007), give some ideas.

GUIDELINES

Facilitating Deep Questioning

Encourage students to think aloud when speaking or writing their explanations as they study or discuss a topic.

Examples

1. Present a challenging story and ask a student to think aloud to explain as he or she reads the story, linking the story to personal experiences and prior knowledge.
2. Have students respond to each other's explanations and consider multiple explanations.
3. Where appropriate, use deliberative argumentation (Chapter 9) to reach a collaborative consensus about what is a good explanation.

Ask questions that require an explanation, not just reciting facts or repeating from the text, to answer.

Examples

1. "How and why would the destruction of bees affect other life on our planet?" "How would the United States have changed if the other candidate had won the Presidential elections in 1860, 1952, and 2016?"

2. Provide models of good, deep questions and teach students to distinguish between deep questions that require explanations like those above and superficial questions that only require a factual answer such as "What insect pollinates flowers?" "Who were the two main Presidential candidates in 1860, 1952, and 2016?"

Ask questions that challenge students' prior beliefs and assumptions.

Examples

1. Ask questions that highlight puzzling or paradoxical situations, such as, "Why is it good for a forest to periodically experience fires?"
2. Ask questions that make students defend their positions with facts and evidence.

To repeat one of my favorite assertions, teachers are not irrelevant in constructivist classrooms. Rather, they are facilitators and learning environment designers. We have explored facilitation. Now let's examine several designs for constructivist teaching and learning: inquiry and problem-based learning, cognitive apprenticeships, and reciprocal teaching.

Inquiry Learning (II, A2, 3)

Inquiry learning is a student-centered approach to learning that predates many "traditional" forms of instruction. Describe the basic structure of this approach to learning. What are its strengths and limitations? What roles does the teacher have?

Inquiry learning Approach in which the teacher presents a puzzling situation and students solve the problem by gathering data and testing their conclusions.

Inquiry and Problem-Based Learning

John Dewey described the basic **inquiry learning** format in 1910. Educators have developed many adaptations of this strategy, but the form usually includes the following elements (Echevarria, 2003; Lashley, Matczynski, & Rowley, 2002). The teacher presents a puzzling event, question, or problem. The students:

- formulate hypotheses to explain the event or solve the problem,
- collect data to test the hypotheses,
- draw conclusions, and
- reflect on the original problem and the thinking processes needed to solve it.

This is a general picture of inquiry learning, but what is actually going on? Erin Furtak and her colleagues (2012) categorized the actual activities and processes in inquiry as being *procedural* (hands-on, posing scientific questions, doing science procedures, collecting data, graphing or charting data), *epistemic* (drawing conclusions based on evidence, generating and revising theories), *conceptual* (connecting to students' prior knowledge, eliciting students' mental models and ideas), or *social* (participating in class discussions, arguing and debating ideas, giving presentations, working collaboratively). When the researchers analyzed 37 studies conducted from 1996 to 2006 that compared inquiry approaches with the traditional teaching of science, they found that the greatest impact on student learning came when the inquiry approach included epistemic

activities or a combination of epistemic, procedural, and social activities. So having students collaborate to do hands-on scientific procedures, gather and represent data, draw conclusions, debate ideas, and make presentations was more effective than traditional teacher-centered approaches. But throughout these activities, teacher guidance and scaffolding were important. Just letting the students work completely on their own doing experiments was not effective.

EXAMPLES OF INQUIRY. Shirley Magnusson and Annemarie Palincsar developed a teachers' guide for planning, implementing, and assessing different phases of inquiry science units, called *guided inquiry supporting multiple literacies* (GisML, see Figure 10.2 on the next page) (Hapgood, Magnusson, & Palincsar, 2004; Palincsar, Magnusson, Collins, & Cutter). The teacher first identifies a curriculum area and some general guiding questions, puzzles, or problems. For example, the teacher chooses *communication* as the area and asks this general question: "How and why do humans and animals communicate?" Next, the teacher poses several specific focus questions: "How do whales communicate?" "How do gorillas communicate?" The focus questions have to be carefully chosen to guide students toward important understandings. One key idea in understanding animal communication is the relationships among the animal's structures, survival functions, and habitat. Animals have specific *structures* such as large ears or echolocators, which *function* to find food, attract mates, or identify predators, and these structures and functions are related to the animals' *habitats*—*large ears for navigating in the dark, for example*. Thus, focus questions must ask about animals with different structures for communication, different functional needs for survival, and different habitats. Questions about animals with the same kinds of structures or the same habitats would not be good focus points for inquiry (Magnusson & Palincsar, 1995).

The next phase is to engage students in the inquiry, perhaps by playing different animal sounds, having students make guesses and claims about communication, and asking the students questions about their guesses and claims. Then, the students conduct both first-hand and second-hand investigations. First-hand investigations are direct experiences and experiments, for example, measuring the size of bats' eyes and ears in relation to their bodies (using pictures or videos—not real bats!). In second-hand investigations, students consult books, the Internet, interviews with experts, and other resources to find specific information or get new ideas. As part of their investigating, the students begin to identify patterns. The curved line in Figure 10.2 shows that cycles can be repeated. In fact, students might go through several cycles of investigating, identifying patterns, and reporting results before moving on to constructing explanations and making final reports. Another possible cycle is to evaluate explanations before reporting by making and then checking predictions, applying the explanation to new situations.

Inquiry teaching allows students to learn content and process at the same time. In the preceding examples, students learned about how animals communicate and how structures are related to habitats. In addition, they learned the inquiry process itself—how to solve problems, evaluate solutions, debate ideas, and think critically.

PROBLEM-BASED LEARNING. Whereas inquiry learning grew out of practices in science, problem-based learning grew out of research on expert knowledge in medicine (Belland, 2011). Through problem-based learning, students develop knowledge that is useful and flexible, not inert. Inert knowledge is information that is memorized but seldom applied (Cognition and Technology Group at Vanderbilt, 1996; Whitehead, 1929).

In **problem-based learning**, students work in groups to confront a real-world, ill-structured problem that has no single correct solution (Belland, Kim, & Hannafin, 2013; Lisette et al., 2014). During the first phase, *initial problem discussion*, the students identify and analyze the problem based on the facts from the scenario, then determine what they already know. It soon becomes clear that the students will need more information, so they identify learning issues. These questions guide the next phase—*individual research* on the learning issues. After the individual research phase, students return to their groups to *report* their research results and *collaborate* to find solutions. As they

Connect and Extend to PRAXIS II®

Discovery Learning (I, A1) Many teachers, especially in mathematics and science, believe that meaningful learning in their content areas is best supported by discovery learning. Be prepared to answer questions about the assumptions, techniques, strengths, and limitations of this instructional strategy.

Problem-based learning Students are confronted with a problem that launches their inquiry as they collaborate to find solutions and learn valuable information and skills in the process.

suggest hypotheses, apply their new knowledge, and evaluate their problem solutions, they may recycle to research again if necessary, and finally reflect on the knowledge and skills they have gained. Throughout the entire process, students are not alone or unguided. Their thinking and problem solving are scaffolded by the teacher, computer software supports, models, coaching, expert hints, guides and organizational aids, or other students in the collaborative groups—so working memory is not overloaded. For example, as students work, they may have to fill in a diagram that helps them distinguish between “claims” and “reasons” in a scientific argument or write on a whiteboard divided into four columns listing *facts*, *ideas*, *learning issues*, and *action plans* (Hmelo-Silver, 2003; Hmelo-Silver, Ravit, & Chinn, 2007).

In true problem-based learning, the problem is real and the students’ actions matter. For example, during the 2010 Deepwater oil spill, many teachers used the problem as a springboard for learning. Their students researched how this spill compared to others in size, location, expense, causes, and attempted solutions. What could be done? How do currents and tides play a role? What locations, businesses, and wildlife are in the greatest danger? What will be the short-term and long-term financial and environmental impacts? What actions can students take to play a positive role? A number of teachers blogged about using the oil spill in problem-based learning and collected resources for other teachers (see edutopia.org/ and search for “oil spill” to find more resources). Let’s look at these phases more closely as they might take place in an upper-level science class (S. S. Klein & Harris, 2007).

1. The cycle begins with an *intriguing challenge* to the whole class. For example, in biomechanics it might be “Assume you are a living cell in a bioreactor. What things will influence how long you live?” or “Your grandmother is recovering from a

FIGURE 10.2

A MODEL TO GUIDE TEACHER THINKING ABOUT INQUIRY-BASED SCIENCE INSTRUCTION

The straight lines show the sequence of phases in instruction, and the curved lines show cycles that might be repeated during instruction.

Source: Based on “Designing a Community of Practice: Principles and Practices of the GisML Community,” by A. S. Palincsar, S. J. Magnusson, N. Marano, D. Ford, and N. Brown, 1998, *Teaching and Teacher Education*, 14, p. 12. Adapted with permission from Elsevier.

broken hip. In which hand should she hold the cane to help her balance?" The question is framed in a way that makes students bring to bear their current knowledge and preconceptions.

2. Next, students *generate ideas* to compile what they currently know and believe and what they need to know more about using individual, small-group, or whole-group brainstorming or other activities.
3. Students research the topic individually. *Multiple perspectives* are added to the process in the form of outside experts (live, on video, or from texts), Web sites, magazine or journal articles, or podcasts on the subject.
4. Students go deeper to *research and revise*. They consult more sources or hear class lectures, all the while revising ideas and perhaps journaling about their thinking.
5. Students *test their mettle* by getting feedback from other students or the teacher about their tentative conclusions. Some formative (ungraded) tests might check their understanding at this point.
6. Students come back to their groups, discuss conclusions, and *go public* with their final conclusions and solutions in the form of an oral presentation, poster/project, or final exam.

The teacher's role in problem-based learning is to identify engaging problems and appropriate resources; orient students to the problem by describing objectives and rationales; organize the students by helping them set goals and define tasks; support, coach, and mentor students as they gather information, craft solutions, and prepare artifacts (models, reports, videos, PowerPoints, portfolios, etc.); and support student reflection on their own learning outcomes and processes (Arends & Kilcher, 2010).

RESEARCH ON INQUIRY AND PROBLEM-BASED LEARNING. Do using inquiry projects or problem-based learning activities lead to greater achievement? The debate has waged for years. Some research results say "yes" (Belland et al., 2013; Furtak et al., 2012; Loyens et al., 2015). But not every educational psychologist agrees that problem-based learning is valuable, at least for all students, as you can see on the next page in the *Point/Counterpoint: Are Inquiry and Problem-Based Learning Effective Teaching Approaches?*

BEING SMART ABOUT PROBLEM-BASED LEARNING. You don't have to choose between inquiry and content-focused methods. The best approach in elementary and secondary schools may be a balance of content-focused and inquiry or problem-based methods (Lisette et al., 2014). For example, Eva Toth, David Klahr, and Zhe Chen (2000) tested a balanced approach for teaching fourth graders how to use the controlled variable strategy in science to design good experiments. The method had three phases: (1) In small groups, students conducted exploratory experiments to identify variables that made a ball roll farther down a ramp; (2) the teacher led a discussion, explained the controlled variable strategy, and modeled good thinking about experiment design; and (3) the students designed and conducted application experiments to isolate which variables caused the ball to roll farther. The combination of inquiry, discussion, explanation, and modeling was successful in helping the students understand the concepts. Clearly, scaffolding supports are key factors in successful inquiry and problem-based learning. As Rich Mayer (2004) has observed, students need enough freedom and exploration to get mentally active and engaged, combined with the right amount of guidance to make the mental activity productive.

The bottom line is that problem-based learning can be effective for helping students learn to solve ill-structured problems if appropriate scaffolding and teacher facilitation are available. For example, teachers can select and limit the number of research materials for the individual research phase, provide models of questions and answers about the learning issues identified, offer guidance about the characteristics of a good solution, and give feedback along the way (Lisette et al., 2014).

Another constructivist approach that relies heavily on scaffolding is cognitive apprenticeships.

POINT/COUNTERPOINT: Are Inquiry and Problem-Based Learning Effective Teaching Approaches?

Inquiry, discovery learning, and problem-based learning are very appealing, but are they effective? Specifically, do these approaches lead to deep understanding and robust knowledge for most students?

POINT

Problem-based learning is overrated. Paul Kirschner and his colleagues were clear and critical in their article in the *Educational Psychologist*. Even the title of the article was blunt: “Why minimal guidance during instruction does not work: An analysis of the failure of constructivist, discovery, problem-based, experiential, and inquiry-based teaching.” They argued:

Although unguided or minimally guided instructional approaches are very popular and intuitively appealing, the point is made that these approaches ignore both the structures that constitute human cognitive architecture and evidence from empirical studies over the past half-century that consistently indicate that minimally guided instruction is less effective and less efficient than instructional approaches that place a strong emphasis on guidance of the student learning process. (Kirschner, Sweller, & Clark, 2006, p. 75)

These respected researchers (and others more recently) cited decades of research demonstrating that unguided

discovery/inquiry and problem-based learning are ineffective, especially for students with limited prior knowledge (Kalyuga, 2011; Klahr & Nigam, 2004; Tobias, 2010). Louis Alfieri and his colleagues (2011) examined the results from 108 studies going back over 50 years and found that explicit teaching was more beneficial than unassisted discovery, especially for studies published in the most well-rated journals. Their conclusion: “unassisted discovery generally does not benefit learning” (p. 12).

But what about problem-based learning in particular? Much of the research on problem-based learning has taken place in medical schools, and results have been mixed. In one study, students learning through problem-based instruction were better at clinical skills such as problem formation and reasoning, but they were worse in their basic knowledge of science and felt less prepared in science (Albanese & Mitchell, 1993). A review of problem-based learning curricula in medical schools concluded that this approach was not effective in promoting higher levels of student knowledge (Colliver, 2000).

Cognitive Apprenticeships and Reciprocal Teaching

Over the centuries, apprenticeships have proved to be an effective form of education. By working alongside a master and perhaps other apprentices, young people have learned many skills, trades, and crafts. Knowledgeable guides provide models, demonstrations, and corrections, as well as a personal bond that is motivating. The performances required of the learner are real and important and grow more complex as the learner becomes more competent (A. Collins, 2006; Hung, 1999; M. C. Linn & Eylon, 2006). With *guided participation* in real tasks comes *participatory appropriation*—students appropriate the knowledge, skills, and values involved in doing the tasks (Rogoff, 1995, 1998). In addition, both the newcomers to learning and the old-timers contribute to the community of practice by mastering and remastering skills—and sometimes improving these skills in the process (Lave & Wenger, 1991).

Allan Collins (2006) suggests that knowledge and skills learned in school have become too separated from their use in the world beyond school. To correct this imbalance, some educators recommend that schools adopt many of the features of apprenticeships. But rather than learning to sculpt or dance or build a cabinet, apprenticeships in school would focus on cognitive objectives such as reading comprehension, writing, or mathematical problem solving. There are many **cognitive apprenticeship** models, but most share six features:

- Students observe an expert (usually the teacher) *model* the performance.
- Students get external support through *coaching* or tutoring (including hints, tailored feedback, models, and reminders).
- Students receive conceptual *scaffolding*, which is then gradually faded as the student becomes more competent and proficient.

Cognitive apprenticeship A relationship in which a less-experienced learner acquires knowledge and skills under the guidance of an expert.

► **Problem-based learning is a powerful teaching approach.** For example, middle school students participating in problem-based learning showed superior comprehension and better reasoning about why the Columbia Shuttle disaster happened compared to those who had just heard a lecture on the topic (Wirkala, & Kuhn, 2011). In a study of almost 20,000 middle school students in a large urban district who used inquiry-based materials, those who participated in inquiry learning had significantly higher passing rates on standardized tests. African American boys especially benefitted from these methods (Geier et al., 2008). Several other studies point to increases in student engagement and motivation with inquiry learning (Hmelo-Silver et al., 2007), as long as the learning is supported and students have adequate background knowledge. In an extensive study of a problem-based medical program in the Netherlands, Schmidt and his colleagues (2009) concluded that compared to graduates of conventional programs, graduates of the problem-based learning program performed better in practical medical and interpersonal skills, took less time to graduate, and had small positive differences in their medical knowledge and diagnostic reasoning. In studies of high school economics and mathematics, research favors problem-based approaches for learning more complex concepts and solving multistep word problems. Students who are better at self-regulation and who know when to ask for help may benefit more from problem-based methods (Evensen, Salisbury-Glennon, & Glenn, 2001), but using problem-based methods over time can help all students to develop these self-directed learning skills.

In sum, Cindy Hmelo-Silver (2004; Hmelo-Silver et al., 2007) reviewed the research and found good evidence that

problem-based learning supports the construction of flexible knowledge and the development of problem-solving and self-directed learning skills, but less evidence indicates that participating in problem-based learning is intrinsically motivating or that it teaches students to collaborate.

Beware of Either/Or The difference between effective and ineffective inquiry and problem-based learning seems to come down to completely unguided discovery versus guided, supported, and well-scaffolded inquiry and problem-based learning. Alfieri and his colleagues (2011) concluded:

[O]ptimal approaches should include at least one of the following: (a) guided tasks that have scaffolding in place to assist learners, (b) tasks requiring learners to explain their own ideas and ensuring that these ideas are accurate by providing timely feedback, or (c) tasks that provide worked examples of how to succeed in the task. (p. 13)

But to make the matter a bit more complicated, evidence shows that the value of guidance and feedback depends on the student's prior knowledge or age. For example, in learning mathematics problem-solving strategies, students with little knowledge benefitted from feedback as they explored possible solutions, but students with some knowledge benefitted more from just exploring solutions independently without feedback and guidance (Fyfe, Rittle-Johnson, & DeCaro, 2012). Also, first-grade students learned some basic mathematics reasoning skills better from unguided discovery learning via computer than from direct instruction—perhaps an example of the value of unstructured play for young children (Baroody et al., 2013).

- Students continually *articulate* their knowledge—putting into words their understanding of the processes and content being learned.
- Students *reflect* on their progress, comparing their problem solving to an expert's performance and to their own earlier performances.
- Students are required to *explore* new ways to apply what they are learning—ways that they have not practiced at the master's side.

As students learn, they are challenged to master more complex concepts and skills and to perform them in many different settings.

How can teaching provide cognitive apprenticeships? Mentoring in teaching is one example. Another is cross-age grouping. In the Key School, an inner-city public elementary school in Indianapolis, Indiana, students of different ages work side by side for part of every day on a “pod” designed to have many of the qualities of an apprenticeship. The pods might focus on a craft or a discipline. Examples include gardening, architecture, and “making money.” Many levels of expertise are evident in the students of different ages, so students can move at a comfortable pace but still have the model of a master available. Community volunteers, including many parents, visit to demonstrate a skill that is related to the pod topic.

COGNITIVE APPRENTICESHIPS IN READING: RECIPROCAL TEACHING. The goal of **reciprocal teaching** is to help students understand and think deeply about what they read (Oczuks, 2003; Palincsar, 1986; Palincsar & Brown, 1984, 1989). To accomplish this goal, students in small reading groups learn four strategies: *summarizing* the content of a passage, *asking a question* about the central point, *clarifying* the difficult parts of the

Reciprocal teaching

Learning to apply the strategies of questioning, summarizing, predicting, and clarifying; designed to help students understand and think deeply about what they read.

material, and *predicting* what will come next. These are strategies skilled readers apply almost automatically but poor readers seldom do—or they don’t know how. To use the strategies effectively, poorer readers need direct instruction, modeling, and practice in actual reading situations.

First, the teacher introduces these strategies, perhaps focusing on one strategy each day. As the expert, the teacher explains and models each strategy and encourages student apprentices to practice. Next, the teacher and the students read a short passage silently. Then, the teacher again provides a model by summarizing, questioning, clarifying, or predicting based on the reading. Everyone reads another passage, and the students gradually begin to assume the teacher’s role. The teacher becomes a member of the group and may finally leave as the students take over the teaching. Often, the students’ first attempts are halting and incorrect. But the teacher gives clues, guidance, encouragement, support doing parts of the task (e.g., providing question stems), modeling, and other forms of scaffolding to help the students master these strategies. The goal is for students to learn to apply these strategies independently.

APPLYING RECIPROCAL TEACHING. Although reciprocal teaching seems to work with almost any age student, most of the research has been done with younger adolescents who can read aloud fairly accurately but who are far below average in reading comprehension. After 20 hours of practice with this approach, many students who were in the bottom quarter of their class moved up to the average level or above on tests of reading comprehension. Palincsar has identified three guidelines for effective reciprocal teaching:

1. *Shift gradually.* The shift from teacher to student responsibility must be gradual.
2. *Match demands to abilities.* The difficulty of the task and the responsibility must match the abilities of each student and grow as these abilities develop.
3. *Diagnose thinking.* Teachers should carefully observe the “teaching” of each student for clues about how the student is thinking and what kind of instruction he or she needs.

In contrast to some approaches that try to teach 40 or more strategies, an advantage of reciprocal teaching is that it focuses attention on four powerful strategies. But these strategies must be taught; not all students develop them on their own. One study of reciprocal teaching spanning over 3 years found that questioning was the strategy used most often, but students had to be taught how to ask good higher-level questions because most student questions were literal or superficial (Hacker & Tenen, 2002). Another advantage of reciprocal teaching is that it emphasizes practicing these four strategies in the context of actual reading—reading literature and reading texts. Finally, the idea of teacher facilitation through scaffolding and gradually moving the student toward independent and fluid reading comprehension is a critical component in reciprocal teaching and cognitive apprenticeships in general (Rosenshine & Meister, 1994). For some vignettes showing reciprocal teaching, go to readingrockets.org and research “reciprocal teaching.”

MyLab Education **Self-Check 10.2**

COLLABORATION AND COOPERATION

Even with all the concern today about test performance and international comparisons, schooling has always been about more than academic learning. Of course, academics are the prime directive, but the ability to collaborate is a core 21st-century capability (Roschelle, 2013).

Most corporations are looking for employees who are not only good at the mastery of a particular set of academic skills but who also have the ability to work harmoniously with a wide variety of coworkers as a cooperative team, to demonstrate initiative and responsibility, and to communicate effectively. (E. Aronson, 2000, p. 91)

Since the 1970s, researchers have examined collaboration and cooperation in schools. Some, like Aronson and Roschelle, believe that learning to successfully collaborate is an important skill in itself, and necessary for success in the future. Other educators claim that collaboration is a means for learning academic material—so we could say the two goals are *learning to collaborate* and *collaborating to learn* (Kuhn, 2015). Of course, teachers don't have to choose. Both goals are valuable.

Despite some inconsistencies, the majority of the studies indicate that truly cooperative groups have positive effects—from preschool to college—on students' empathy, tolerance for differences, feelings of acceptance, friendships, self-confidence, awareness of the perspectives of others, higher-level reasoning, problem solving, decision making, essay writing, and even school attendance (Galton, Hargreaves, & Pell, 2009; Gillies & Boyle, 2011; Solomon, Watson, & Battistich, 2001; Zhang et al., 2016). It is even argued that cooperative learning experiences are crucial in preventing many of the social problems that plague children and adolescents (Gillies, 2003, 2004). About 80% of elementary school teachers and 62% of middle school teachers use some form of peer learning on a regular basis (Ladd et al., 2014b).

COLLABORATION, GROUP WORK, AND COOPERATIVE LEARNING. The terms *collaboration*, *group work*, and *cooperative learning* often are used as if they mean the same thing. Certainly there is some overlap, but there are differences as well. Ted Panitz (1996) suggests **collaboration** is a philosophy about how to relate to others—how to learn and work. Collaboration is a way of dealing with people that respects differences, shares authority, and builds on the knowledge that is distributed among other people. **Cooperation**, on the other hand, is a way of working with others to attain a shared goal (Gillies, 2003). Collaborative learning has roots in the work of British teachers who wanted their students to respond to literature in more active ways as they learned. Cooperative learning has American roots in the work of psychologists John Dewey and Kurt Lewin. You could say that *cooperative learning* is one way to *collaborate* in schools.

Group work, on the other hand, is simply several students working together—they may or may not be cooperating. Many activities can be completed in groups. For example, students can divide up the territory to conduct a local survey. How do people feel about the plan to build a new mall that will bring more shopping and more traffic? Would the community support or oppose the building of a nuclear power plant? If students must learn 10 new definitions in a biology class, why not let them divide up the terms and definitions and teach one another? Be sure, however, that everyone in the group can handle the task. Sometimes, one or two students end up doing the work of the entire group.

Group work can be useful, but true cooperative learning requires much more than simply putting students in groups and dividing up the work. Angela O'Donnell and Jim O'Kelly, colleagues of mine from Rutgers University, describe a teacher who claimed to be using “cooperative learning” by asking students to work in pairs on a paper, each writing one part. Unfortunately, the teacher allowed no time to work together and provided no guidance or preparation in cooperative social skills. Students got a grade for their individual part and a group grade for the whole project. One student received an A for his part, but a C for the group project because his partner earned an F—he never turned in any work. So one student was punished with a C for a situation he could not control while the other was rewarded with a C for doing no work at all. This was not cooperative learning—it wasn't even group work (O'Donnell & O'Kelly, 1994).

BEYOND GROUPS TO COOPERATION. David and Roger Johnson (2009a), two of the founders of cooperative learning in the United States, define formal **cooperative learning** as “students working together, for one class period to several weeks, to achieve shared learning goals and complete jointly specific tasks and assignments” (p. 373). The Johnson brothers describe five elements that define true cooperative learning groups:

- Positive interdependence
- Promotive interaction

Connect and Extend to PRAXIS II®

Characteristics of Cooperative Learning (II, A2)

Many instructional strategies labeled as *cooperative learning* lack one or more qualities that are essential components of such techniques. List those essential qualities, and explain the role of each.

MyLab Education Podcast 10.1

Textbook author Anita Woolfolk shares some ways that she has used cooperative learning in her college classes to take advantage of students as experts in technology.

Collaboration A philosophy about how to relate to others—how to learn and work.

Cooperation Way of working with others to attain a shared goal.

Cooperative learning Situations in which elaboration, interpretation, explanation, and argumentation are integral to the activity of the group and where learning is supported by other individuals.

- Individual accountability
- Collaborative and social skills
- Group processing

Group members experience *positive interdependence*. The members believe they can attain their goals only if the others in the group attain their goals as well, so they need each other for support, explanations, and guidance. *Promotive interaction* means that group members encourage and facilitate each other's efforts. They usually interact face-to-face and close together, not across the room, but they also could interact via digital media around the world. Even though they feel a responsibility to the group to work together and help each other, students must ultimately demonstrate learning on their own; they are held *individually accountable* for learning, often through individual tests or other assessments.

Collaborative and social skills are necessary for effective group functioning. These skills include paying attention and listening even if you don't agree, disagreeing and sharing your ideas respectfully, taking turns, doing your fair share, working with partners even if they are not your choice, asking for/providing help, giving constructive feedback, reaching consensus, involving every member, encouraging and praising, controlling emotions and frustrations, cheering up partners, and admitting mistakes, among other skills (Ladd et al., 2014a, 2014b). These skills are not natural, even for socially capable students. Often they must be taught and practiced before the groups tackle a learning task. Finally, members monitor *group processes* and relationships to make sure the group is working effectively and to learn about the dynamics of groups. They take time to ask, "How are we doing as a group? Is everyone working together? What should we do more or less of next time?"

Different learning theory approaches favor cooperative learning for different reasons (O'Donnell, 2002, 2006). Information processing theorists point to the value of group discussion in helping participants rehearse, elaborate, and expand their knowledge. As group members question and explain, they have to organize their knowledge, make connections, and review—all processes that support information processing and memory. Advocates of a Piagetian perspective suggest the interactions in groups can create the cognitive conflict and disequilibrium that lead an individual to question his or her understanding and try out new ideas—or, as Piaget (1985) said, "to go beyond his current state and strike out in new directions" (p. 10). Those who favor Vygotsky's theory suggest that social interaction is important for learning because higher mental functions such as reasoning, comprehension, and critical thinking originate in social interactions and are then appropriated and internalized by individuals. Students can accomplish mental tasks with social support before they can do them alone. Thus, cooperative learning provides the social support and scaffolding students need to move learning forward. To benefit from these dimensions of cooperative learning, groups must be cooperative—all members must participate.

Cooperative learning has a long history in American education, moving in and out of favor over the years. Today, evolving constructivist perspectives have fueled a growing commitment to cooperative learning. The approach is now used "in schools and universities throughout most of the world in every subject area and from pre-school through graduate school and adult training programs" (D. Johnson & R Johnson, 2009, p. 365). Research supports this wide use. For example, in grades 8 through 12 in Australia, students in cooperative groups that were structured to require positive interdependence and mutual helping learned more in math, science, and English than students in unstructured learning groups (Gillies, 2003). In addition, compared to students in the unstructured groups, students in the structured groups also said learning was more fun.

But, as any teacher or parent knows, cooperation is not automatic when students are put into groups.

WHAT CAN GO WRONG: MISUSES OF GROUP LEARNING. Without careful planning and monitoring by the teacher, group interactions can hinder learning and reduce rather

than improve social relations in classes (Gillies & Boyle, 2011; Kuhn, 2015). For example, if there is pressure in a group for conformity—perhaps because rewards are being misused or one student dominates the others—interactions can be unproductive and unreflective. Without feedback about accuracy, misconceptions might be reinforced, or the worst, not the best, ideas may be combined to construct a superficial or even incorrect understanding (Asterhan, Schwarz, & Cohen-Eliyahu, 2014). Students who work in groups but arrive at wrong answers may be more confident that they are right—a case of “two heads are worse than one” (Puncochar & Fox, 2004). Also, the ideas of low-status students may be ignored or even ridiculed while the contributions of high-status students are accepted and reinforced, regardless of the merit of either set of ideas (C. W. Anderson, Holland, & Palincsar, 1997; E. G. Cohen, 1986). Mary McCaslin and Tom Good (1996) list several other disadvantages of group learning:

- Students often value the process or procedures over the learning. Speed and finishing early take precedence over thoughtfulness and learning.
- Socializing and interpersonal relationships may take precedence over learning.
- Students may simply shift dependency from the teacher to the “expert” in the group; learning is still passive, and what is learned can be wrong.
- Status differences may be increased rather than decreased. Some students learn to “loaf” because the group progresses with or without their contributions. Others become even more convinced that they are unable to understand without the support of the group.

Deanna Kuhn (2015) sums up the situation: “It is not enough to put individuals in a context that allows collaboration and expect them to engage in it effectively. Intellectual collaboration is a skill, learned through engagement and practice and much trial and error” (p. 51). Without careful attention to task design and support for cooperation, students probably won’t benefit from collaborative activities.

How can teachers avoid these problems and encourage true cooperation? Like any instructional activity, cooperative learning has three phases that require teachers’ preparation and participation: before, during, and after the lesson. To insure successful cooperative learning, teachers have to plan *before*; monitor, support, and consolidate learning *during*; and reflect on learning *after* the activity, as shown in Table 10.3.

TABLE 10.3 • The Teacher’s Role in Cooperative Learning

Here are some examples of teacher competencies needed for successful cooperative learning. The teacher plans, monitors, supports, consolidates, and finally reflects.

BEFORE THE ACTIVITY	DURING THE ACTIVITY			AFTER THE ACTIVITY
<i>Plan/Design</i>	<i>Monitor</i>	<i>Support</i>	<i>Consolidate</i>	<i>Reflect</i>
Goals/Tasks Materials Group composition Roles/Scripts Instructions Planned assessments	Determine which interactions will lead to learning in this task. Watch for explanations, questions, challenges, shared information, elaboration, and affirmations.	Scaffolding and fading Prompts, cues Resources at different levels Encouragement Feedback Praise Guiding questions	Class presentations Compare/contrast solutions Whole class discussion Individual testing	Revisit learning goals and plans: What did monitoring reveal? Was the support appropriate? Did students learn? What changes should be made for the next time?

Source: Based on Kaendler, C., Wiedmann, M., Rummel, N., & Spada, H. (2015). Teacher Competencies for the Implementation of Collaborative Learning in the Classroom: A Framework and Research Review. *Educational Psychology Review*, 27, 505–536.

Tasks for Cooperative Learning

Successful teachers interviewed in one study emphasized that group activities must be well planned, students need to be prepared to work in groups, and teachers' expectations for the task have to be explicitly stated (Gillies & Boyle, 2011). Like so many other decisions in teaching, plans for using cooperative groups begin with a goal. What are students supposed to accomplish? What is the task? Is it a true group task—one that builds on the knowledge and skills of several students—or is the task more appropriate for individuals (E. G. Cohen, 1994; O'Donnell, 2006)?

Tasks for cooperative groups may be more or less structured. Highly structured tasks include work that has specific answers—drill and practice, applying routines or procedures, answering questions from readings, computations in mathematics, and so on. Ill-structured complex tasks have multiple answers and unclear procedures, requiring problem finding and higher-order thinking. These ill-structured problems are true group tasks; that is, they are likely to require the resources (knowledge, skills, problem-solving strategies, creativity) of all the group members to accomplish, whereas individuals often can accomplish highly structured tasks just as effectively as groups. These distinctions are important because ill-structured, complex, true group tasks appear to require more and higher-quality interactions than routine tasks if learning and problem solving are to occur (E. G. Cohen, 1994; Gillies, 2004; Gillies & Boyle, 2011).

HIGHLY STRUCTURED, REVIEW, AND SKILL-BUILDING TASKS. A relatively structured task such as reviewing previously learned material for an exam might be well served by a structured technique such as *student teams achievement divisions* (STAD), in which teams of four students compete to determine which team's members can amass the greatest improvement over previous achievement levels (Slavin, 1995). Praise, recognition, or extrinsic rewards can enhance motivation, effort, and persistence under these conditions, and thus increase learning. Focusing the dialogue by assigning narrow roles also may help students stay engaged when the tasks involve practice or review.

ILL-STRUCTURED, CONCEPTUAL, AND PROBLEM-SOLVING TASKS. If the task is ill structured and more cognitive in nature, then an open exchange and elaborated discussion will be more helpful (E. G. Cohen, 1994; Ross & Raphael, 1990). Thus, strategies that encourage extended and productive interactions are appropriate when the goal is to develop higher-order thinking and problem solving. In these situations, a tightly structured process, competition among groups for rewards, and rigid assignment of roles are likely to inhibit the richness of the students' interactions and to interfere with progress toward the goal. Open-ended techniques such as reciprocal questioning (King, 1994), reciprocal teaching (Palincsar & Brown, 1984; Rosenshine & Meister, 1994), pair-share (S. Kagan, 1994), or Jigsaw (E. Aronson, 2000) should be more productive because, when used appropriately, they encourage more extensive interaction and elaborative thought in situations where students are being exposed to complex materials. In these instances, the use of rewards may well divert the group away from the goal of in-depth cognitive processing. When rewards are offered, the goal often becomes achieving the reward as efficiently as possible, which could mean having the highest-achieving students do all the work (Webb & Palincsar, 1996).

SOCIAL SKILLS AND COMMUNICATION TASKS. When the goal of peer learning is enhanced social skills or increased intergroup understanding and appreciation of diversity, the assignment of specific roles and functions within the group might support communication (E. G. Cohen, 1994; S. Kagan, 1994). In these situations, it can be helpful to rotate leadership roles so that minority group students and females have the opportunity to demonstrate and develop leadership skills; in addition, all group members can experience the leadership capabilities of each individual (N. Miller & Harrington, 1993). Rewards probably are not necessary, and they may actually get in the way because the goal is to build community, a sense of respect, and responsibility for all team members.

Setting Up Cooperative Groups

How large should a cooperative group be? Again, the answer depends on your learning goals. If the purpose is for the group members to review, rehearse information, or practice, 4 to 5 or 6 students is about the right size. But if the goal is to encourage each student to participate in discussions, problem solving, or computer learning, then groups of 2 to 4 members work best. Also, when setting up cooperative groups, it often makes sense to balance the number of boys and girls. Some research indicates that when there are just a few girls in a group, they tend to be left out of the discussions unless they are the most able or assertive members. By contrast, when there are only one or two boys in the group, they tend to dominate and be “interviewed” by the girls unless these boys are less able than the girls or are very shy. Whatever the case, teachers must monitor groups to make sure everyone is contributing and learning.

If a group includes some students who are perceived as different or who are often rejected, then it makes sense to be sure that there are group members who are tolerant and kind. One successful teacher interviewed by Gillies and Boyle (2011) put it this way:

I also try to make sure that there are one or two people in the group who have the ability to be tolerant. At least the kid in question will know that, while the other group members may not be his best friends, they won't give him a hard time. I try to put the least reactive kids in the group with the child in question. This year I've had a couple of girls who have been very good with difficult kids. They don't put up with nonsense but they don't over-react and are prepared to demonstrate some good social skills. (p. 72)

ASSIGNING ROLES. Some teachers assign roles to students to encourage cooperation and full participation. Several roles are described in Table 10.4. If you use roles, be sure that they support learning. In groups that focus on social skills, roles should

TABLE 10.4 • Possible Student Roles in Cooperative Learning Groups

Depending on the purpose of the group and the age of the participants, having these assigned roles might help students cooperate and learn. Of course, students may have to be taught how to enact each role effectively, and roles should be rotated so students can participate in different aspects of group learning.

ROLE	DESCRIPTION
Encourager	Encourages reluctant or shy students to participate
Praiser/Cheerleader	Shows appreciation of others' contributions, and recognizes accomplishments
Gate Keeper	Equalizes participation, and makes sure no one dominates
Coach	Helps with the academic content, explains concepts
Question Commander	Makes sure all students' questions are asked and answered
Checker	Checks the group's understanding
Taskmaster	Keeps the group on task
Recorder	Writes down ideas, decisions, and plans
Reflector	Keeps group aware of progress (or lack of progress)
Quiet Captain	Monitors noise level
Materials Monitor	Picks up and returns materials

support listening, encouragement, and respect for differences. In groups that focus on practice, review, or mastery of basic skills, roles should support persistence, encouragement, and participation. In groups that focus on higher-order problem solving or complex learning, if you assign roles, they should encourage thoughtful discussion, sharing of explanations and insights, probing, brainstorming, and creativity. Make sure that you don't communicate to students that the major purpose of the groups is simply to do the procedures—the roles. Roles are supports for learning, not ends in themselves (Woolfolk Hoy & Tschannen-Moran, 1999).

Often, cooperative learning strategies include group reports to the entire class. If you have been on the receiving end of these class reports, you know that they can be deadly dull. To make the process more useful for the audience as well as the reporters, Annemarie Palincsar and Leslie Herrenkohl (2002) taught the class members to use *intellectual roles* as they listened to reports. These roles were based on the scientific strategies of predicting and theorizing, summarizing results, and relating predictions and theories to results. Some audience members were assigned the role of checking the reports for clear relationships between predictions and theories. Other students in the audience listened for clarity in the findings. And the rest of the students were responsible for evaluating how well the group reports linked prediction, theories, and findings. Research shows that using these roles promotes class dialogue and conceptual understanding (Palincsar & Herrenkohl, 2002).

GIVING AND RECEIVING EXPLANATIONS. In practice, the effects of learning in a group vary, depending on what actually happens in the group and who is in it. If only a few people take responsibility for the work, these people will learn, but the nonparticipating members probably will not. Students who ask questions, get answers, and attempt explanations are more likely to learn than students whose questions go unasked or unanswered. In fact, evidence shows that the more a student provides elaborated, thoughtful explanations to other students in a group, the more the *explainer* learns. Giving good explanations appears to be even more important for learning than receiving explanations (O'Donnell, 2006; Webb, Farivar, & Mastergeorge, 2002). In order to explain, you have to organize the information, put it into your own words, think of examples and analogies (which connect the information to things you already know), and test your understanding by answering questions. These are excellent learning strategies (King, 2002; O'Donnell & O'Kelly, 1994).

Good explanations are relevant, timely, correct, and elaborated enough to help the listener correct misunderstandings; the best explanations tell why (Webb et al., 2002; Webb & Mastergeorge, 2003). For example, in a middle school mathematics class, students worked in groups on problems like this:

Find the cost of a playing a video game for 20-minutes when the first minute costs \$0.25 and each additional minute costs \$0.11.

The level of explanation and help students received was significantly related to learning; the higher the level, the more learning. At the highest level, the helper tells how to solve the problem and *why*. For example, a helper explaining the problem above might say, “OK, it is 25 cents for the first minute, then there are 19 minutes left and each of those minutes costs 11 cents, so you multiply 11 cents by 19. That equals \$2.09—then add 25 cents for the first minute so it costs \$2.34.” A poor explanation might be just giving the solution, “11 times 19 plus 25” or even just provide the answer—“I got \$2.34.” If a helper says, “11 times 19,” then the receiver should say, “Why is it 19?” or “Why do you multiply by 11?” Asking good questions and giving clear explanations are critical, and usually these skills must be taught.

Designs for Cooperation

Developing deep understandings in cooperative groups requires that all the group members *participate* in *high-quality discussions* that include interpretations, connections, explanations, and evidence supporting claims. We now turn to different strategies that build in structures to support both participation and high-quality discussions.

FIGURE 10.3**QUESTION STEMS TO ENCOURAGE DIALOGUE
IN RECIPROCAL QUESTIONING**

After participating in a lesson or studying an assignment on their own, students use these stems to develop questions, create and compare answers, and collaborate to create the best response.

What is an everyday application of _____?

How would you define _____ in your own words?

What are the advantages and disadvantages of _____?

What do you already know about _____?

Explain why _____ applies to _____.

How does _____ influence _____?

What is the value of _____?

What are the reasons for _____?

What are some arguments for and against _____?

What is your first choice about _____? Your second choice? _____? Why?

What if _____ and why?

Compare _____ and _____ based only on _____.

How would _____ be different if _____?

Do you agree or disagree with this claim _____? What is your evidence?

RECIPROCAL QUESTIONING. Reciprocal questioning requires no special materials or testing procedures and can be used with a wide range of ages. After a lesson or presentation by the teacher, students work in pairs or triads to ask and answer questions about the material (King, 1990, 1994, 2002). The teacher provides question stems (see Figure 10.3), and then students are taught how to develop specific questions about the lesson material using the generic question stems. The students create questions and then take turns asking and answering. This process has proved more effective than traditional discussion groups because it seems to encourage deeper thinking about the material as well as forming connections between the lesson and previous knowledge or experience.

For example, using question stems like those in Figure 10.3, a small group in Mr. Garcia's ninth-grade world cultures class had the following discussion about the concept of culture:

Sally: In your own words, what does culture mean?

Jim: Well, Mr. Garcia said in the lesson that a culture is the knowledge and understandings shared by the members of a society. I guess it's all the things and beliefs and activities that people in a society have in common. It includes things like religion, laws, music, medical practices, stuff like that.

Sally: And dance, art, family roles.

Barry: Knowledge includes language. So, I guess cultures include language, too.

Jim: I guess so. Actually, I have a question about that: How does a culture influence the language of a society?

Barry: Well, for one thing, the language is made up of words that are important to the people of that culture. Like, the words name things that the people care about, or need, or use. And so, different cultures would have different vocabularies. Some cultures may not even have a word for *telephone*, because they don't have any. But, phones are important in our culture, so we have lots of

Reciprocal questioning
Students work in pairs or triads to ask and answer questions about lesson material.

different words for phones, like *cell phone*, *digital phone*, *desk phone*, *cordless phone*, *phone machine*, and . . .

Jim (laughing): I'll bet desert cultures don't have any words for *snow* or *skiing*.

Sally (turning to Barry): What's your question?

Barry: I've got a great question! You'll never be able to answer it. What would happen if there were a group somewhere without any spoken language? Maybe they were all born not being able to speak, or something like that. How would that affect their culture, or could there even be a culture? (King, 2002, pp. 34–35)

JIGSAW. Elliot Aronson and his graduate students invented the **Jigsaw classroom** when Aronson was a professor of social psychology (and I was a student) at the University of Texas at Austin. Some of my friends worked on his research team. Aronson developed the approach “as a matter of absolute necessity to help defuse a highly explosive situation” (E. Aronson, 2000, p. 137). The Austin schools had just been desegregated by court order. White, African American, and Hispanic students were together in classrooms for the first time. Hostility and turmoil ensued, with fistfights in corridors and classrooms. Aronson's answer was the Jigsaw Classroom.

In Jigsaw, each group member is given part of the material to be learned by the whole group. Students become “experts” on their piece. Because students have to learn and be tested on every piece of the larger “puzzle,” everyone's contribution is important—the students truly are interdependent. A more recent version, Jigsaw II, adds expert groups in which the students who are responsible for the same material from each learning group confer to make sure they understand their assigned part and then plan ways to teach the information to their learning group members. Next, students return to their learning groups, bringing their expertise to the sessions. In the end, students take an individual test covering all the material and earn points for their learning team score. Teams can work for rewards or simply for recognition (E. Aronson, 2000; Slavin, 1995).

CONSTRUCTIVE/STRUCTURED CONTROVERSIES. Constructive conflict resolution is essential in classrooms because conflicts are inevitable and even necessary for learning. Piaget's theory tells us that developing knowledge requires disequilibrium—cognitive conflict. Sidney D'Mello and his colleagues (2014) suggest that confusion can stimulate complex learning as long as students engage to resolve the conflict. One study of tenth graders found that students who were wrong, but for different reasons, were sometimes able to correct their misunderstandings if they argued together about their conflicting wrong answers (Schwarz, Neuman, & Biezuner, 2000). Individuals trying to exist in groups will have interpersonal conflicts, too, which also can lead to learning. In fact, research over the last 40 years demonstrates that **constructive/structured controversy** in classrooms can lead to greater learning, open-mindedness, seeing the perspectives of others, creativity, motivation, engagement, and self-esteem (D. W. Johnson & Johnson, 2009b; Roseth, Saltarelli, & Glass, 2011). Table 10.5 shows how academic and interpersonal conflicts can be positive forces in a learning community.

As you can see in Table 10.5, the structured part of *constructive/structured controversies* is that students work in pairs within their four-person cooperative groups to research a particular controversy, such as whether lumber companies should be allowed to cut down trees in national forests. Each pair of students researches the issue, develops a pro or con position, presents that position and evidence to the other pair, discusses the issue, and then reverses positions and argues for the other perspective. Then, the group develops a final report that summarizes the best arguments for each position and reaches a consensus (D. W. Johnson & Johnson, 2009b; O'Donnell, 2006).

In addition to these approaches, Spencer Kagan (1994) has developed many cooperative learning structures designed to accomplish different kinds of academic and social tasks.

Connect and Extend to PRAXIS II®

Forms of Cooperative Learning (II, A2)

STAD and Jigsaw are just two of many cooperative learning techniques, each designed for certain instructional purposes.. For ideas that are especially appropriate for older students, go to the Center for Teaching Excellence at Cornell University (cte.cornell.edu/) and search for “collaborative learning” or to the University of Tennessee at Chattanooga (utc.edu) and search for “cooperative learning/”

Jigsaw classroom A

learning process in which each student is part of a group and each group member is given part of the material to be learned by the whole group. Students become “expert” on their piece and then teach it to the others in their group.

Constructive/Structured controversy

Students work in pairs within their four-person cooperative groups to research a particular controversy.

TABLE 10.5 • Constructive/Structured Controversies: Learning from Academic and Interpersonal Conflicts

Conflict, if handled well, can support learning. Academic conflicts can lead to critical thinking and conceptual change. Conflicts of interest are unavoidable but can be handled so no one is the loser.

CONSTRUCTIVE ACADEMIC CONTROVERSY	CONFLICTS OF INTEREST
One person's ideas, information, theories, conclusions, and opinions are incompatible with those of another, and the two seek to reach an agreement.	The actions of one person attempting to maximize his or her benefits prevents, blocks, or interferes with another person's maximizing her or his benefits.
<i>Controversy Procedure</i>	<i>Integrative (Problem-Solving) Negotiations</i>
Research and prepare positions.	Describe wants.
Present and advocate positions.	Describe feelings.
Refute opposing position and refute attacks on own position.	Describe reasons for wants and feelings.
Reverse perspectives.	Take other's perspective.
Synthesize and integrate best evidence and reasoning from all sides.	Invent three optional agreements that maximize joint outcomes. Choose one, and formalize agreement.

Reaching Every Student: Using Cooperative Learning Wisely

Cooperative learning always benefits from careful planning, but sometimes including students with special needs requires extra attention to planning and preparation. For example, cooperative structures such as scripted questioning and peer tutoring depend on a balanced interaction between the person taking the role of questioner or explainer and the student who is answering or being taught. In these interactions, you want to see and hear explaining and teaching, not just telling or giving right answers. But many students with learning disabilities have difficulties understanding new concepts, so both the explainer and the student can get frustrated, and social rejection for the student with learning disabilities might follow. Because students with learning disabilities often have problems with social relations, it is not a good idea to put them in situations where more rejection is likely. So, when you are teaching new or difficult-to-grasp concepts, cooperative learning might not be the best choice for students with learning disabilities (Kirk et al., 2006). In fact, research has found that cooperative learning in general is not always effective for students with learning disabilities (D. D. Smith, 2006).

Gifted students also may not benefit from cooperative learning when groups are mixed in ability. The pace often is too slow, the tasks too simple, and there is just too much repetition. In addition, gifted students often fall into the role of teacher or end up just doing the work quickly for the whole group. If you use mixed-ability groups and include gifted students, the challenges are to use complex tasks that allow work at different levels and keep gifted students engaged without losing the rest of the class (D. D. Smith, 2006).

Cooperative learning may be an excellent choice for students who are English language learners (ELLs), however. The Jigsaw cooperative structure is especially helpful because all students in the group, including the students who are ELLs, have information that the group needs, so they also must talk, explain, and interact. In fact, the Jigsaw approach was developed in response to the need to create high interdependence in diverse groups. In many classrooms today, four to six or more languages are

GUIDELINES

Using Cooperative Learning

Fit group size and composition to your learning goals.

Examples

1. For social skills and team-building goals, use groups of two to five, common interest groups, mixed groups, or random groups.
2. For structured, fact- and skill-based, practice-and-review tasks, use groups of 4 to 6, mixed-ability such as high-middle and middle-low or high-low and middle-middle group compositions.
3. For higher-level conceptual and thinking tasks, use groups of two to four; select members to encourage interaction.

Assign appropriate roles.

Examples

1. For social skills and team-building goals, assign roles to monitor participation and conflict; rotate leadership of the group.
2. For structured fact- and skill-based, practice-and-review tasks, assign roles to monitor engagement and ensure low-status students have resources to offer, as in Jigsaw.
3. For higher-level conceptual and thinking tasks, assign roles only to encourage interaction, divergent thinking, and extended, connected discourse, as in debate teams, or to assign a group facilitator. Don't let roles get in the way of learning.

Make sure you assume a supporting role as the teacher.

Examples

1. For social skills and team-building goals, be a model and encourager.
2. For structured fact- and skill-based, practice-and-review tasks, be a model, director, or coach.

3. For higher-level conceptual and thinking tasks, be a model and facilitator.

Move around the room, and monitor the groups.

Examples

1. For social skills and team-building goals, watch for listening, turn taking, encouraging, and managing conflict.
2. For structured fact- and skill-based, practice-and-review tasks, watch for questioning, giving multiple elaborated explanations, attention, and practice.
3. For higher-level conceptual and thinking tasks, watch for questioning, explaining, elaborating, probing, divergent thinking, providing rationales, synthesizing, and using and connecting knowledge sources.

Start small and simple until you and the students know how to use cooperative methods.

Examples

1. For social skills and team-building goals, try one or two skills, such as listening and paraphrasing.
2. For structured fact- and skill-based, practice-and-review tasks, try pairs of students quizzing each other.
3. For higher-level conceptual and thinking tasks, try reciprocal questioning using pairs and just a few question stems.

For more information on cooperative learning, see:

Source: Based on "Implications of Cognitive Approaches to Peer Learning for Teacher Education," by A. Woolfolk Hoy and M. Tschannen-Moran, 1999. In A. O'Donnell and A. King (Eds.), *Cognitive Perspectives on Peer Learning*. Mahwah, NJ: Lawrence Erlbaum.

represented. Teachers can't be expected to master every heritage language spoken by all of their students every year. In these classrooms, cooperative groups can help as students work together on academic tasks. Students who speak two languages can help translate and explain lessons to others in the group. Speaking in a smaller group may be less anxiety provoking for students who are learning another language; so the students who are ELLs may get more language practice with feedback in these groups (D. D. Smith, 2006). The *Guidelines: Using Cooperative Learning* give you ideas for using cooperative learning with all your students..

Cooperative learning is only as good as its design and implementation. Cooperative methods probably are both misused and underused in schools, in part because using cooperative learning well requires time and investment in teaching students how to learn in groups (Kuhn, 2015; Blatchford, Baines, Rubie-Davies, Bassett, & Chowne, 2006).

Dilemmas of Constructivist Practice

Years ago, Larry Cremin (1961) observed that progressive, innovative pedagogies require infinitely skilled teachers. Today, the same could be said about constructivist teaching. We have already seen that many varieties of constructivism and many practices flow

TABLE 10.6 • Teachers' Dilemmas of Constructivism in Practice

Teachers face conceptual, pedagogical, cultural, and political dilemmas as they implement constructivist practices. Here are explanations of these dilemmas and some representative questions that teachers face as they confront them.

TEACHERS' DILEMMA CATEGORY	REPRESENTATIVE QUESTIONS OF CONCERN
I. <i>Conceptual dilemmas</i> : Grasping the underpinnings of cognitive and social constructivism; reconciling current beliefs about pedagogy with the beliefs necessary to support a constructivist learning environment.	Which version of constructivism is suitable as a basis for my teaching? Is my classroom supposed to be a collection of individuals working toward conceptual change or a community of learners whose development is measured by participation in authentic disciplinary practices? If certain ideas are considered correct by experts, should students internalize those ideas instead of constructing their own?
II. <i>Pedagogical dilemmas</i> : Honoring students' attempts to think for themselves while remaining faithful to accepted disciplinary ideas; developing deeper knowledge of subject matter; mastering the art of facilitation; managing new kinds of discourse and collaborative work in the classroom.	Do I base my teaching on students' existing ideas rather than on learning objectives? What skills and strategies are necessary for me to become a facilitator? How do I manage a classroom where students are talking to one another rather than to me? Should I place limits on students' construction of their own ideas? What types of assessments will capture the learning I want to foster?
III. <i>Cultural dilemmas</i> : Becoming conscious of the culture of your classroom; questioning assumptions about what kinds of activities should be valued; taking advantage of experiences, discourse patterns, and local knowledge of students with varied cultural backgrounds.	How can we contradict traditional, efficient classroom routines and generate new agreements with students about what is valued and rewarded? How do my own past images of what is proper and possible in a classroom prevent me from seeing the potential for a different kind of learning environment? How can I accommodate the worldviews of students from diverse backgrounds while at the same time transforming my own classroom culture? Can I trust students to accept responsibility for their own learning?
IV. <i>Political dilemmas</i> : Confronting issues of accountability with various stakeholders in the school community; negotiating with key others the authority and support to teach for understanding.	How can I gain the support of administrators and parents for teaching in such a radically different and unfamiliar way? Should I make use of approved curriculums that are not sensitive enough to my students' needs, or should I create my own? How can diverse problem-based experiences help students meet specific state and local standards? Will constructivist approaches adequately prepare my students for high-stakes testing for college admissions?

Source: M. Windschitl. (2002). Framing Constructivism in Practice as the Negotiation of Dilemmas: An Analysis of the Conceptual, Pedagogical, Cultural, and Political Challenges Facing Teachers. *Review of Educational Research*, 72, p. 133. Copyright © 2002 by the American Educational Research Association. Reproduced with permission of the publisher.

from these different conceptions. We also know that all teaching today happens in a context of high-stakes testing and accountability. In these situations, constructivist teachers face many challenges. Mark Windschitl (2002) identified four teacher dilemmas of constructivism in practice, summarized in Table 10.6.

DESIGNING LEARNING ENVIRONMENTS IN A DIGITAL WORLD

It seems that computers, smart phones, iPads, tablets, digital readers, wikis, and interactive video games, along with iCloud, Facebook, Twitter, Google, WhatsApp, Snapchat, Instagram, Scratch, . . . and other digital tools and media have changed life for everyone. Homes and schools are filled with media. Many of your students will have had computers, even from early ages. Their immersion in virtual reality games may make traditional school activities seem tame and boring by comparison (Common Sense Media, 2013; Connor-Zachocki, Husbye, & Gee, 2015; Graesser, 2013; Lenhart, 2015; Turkle, 2011).

STOP & THINK How many digital devices are you using right now? How many do you own? •

MyLab Education
Video Example 10.4

In this video, high school students develop instruction for younger students to help them learn appropriate and safe behaviors for online exchanges. As you watch, consider how technology supports learning.

For many students, doing homework often involves exchanging messages with friends via email, texting, or cell phones, searching the Web, and downloading resources—all the time listening to music via a phone (D. F. Roberts, Foehr, & Rideout, 2005). These students have never known a world without digital media, so they have been called *digital natives*, *homo zappiens*, *the Net generation*, *iGenerations*, or *Google Generation* (Kirschner & van Merriënboer, 2013). Students are at least as expert at using technology as their teachers and most of this expertise was acquired outside of school (Graesser, 2013).

Technology and Learning

Does technology use support academic learning? The answer is complex and even surprising. One review concluded that using computer tutorial programs appeared to improve achievement test scores for K–12 students, but simulations and enrichment programs had few effects—perhaps another example that when you teach and test specific skills, children learn the skills. Computers are more likely to increase achievement if they support the basic processes that lead to learning: active engagement, frequent interaction with feedback, authenticity and real-world connection, and productive group work (Graesser, 2013; A. Jackson et al., 2006; Tamim, Bernard, Borokhovski, Abrami, & Schmid, 2011). Computers can be useful to teach basic reading processes such as word decoding or phonological awareness or basic number sense because specialized software can provide individual feedback, move at the right pace for each student, and increase motivation. Well-designed programs also can improve listening and reading comprehension (Barody et al., 2013; Potocki, Ecalle, & Magnan, 2013; R. Savage et al., 2013). Like any teaching tool, computers can be effective if used well, but just being on a computer will not automatically increase academic achievement.

TECHNOLOGY-RICH ENVIRONMENTS. With all the technology available today, interest in technology-rich learning environments (TREs) is growing. These environments include virtual worlds, computer simulations that support problem-based learning, intelligent tutoring systems, educational games, audio recordings, wikis, hand-held wireless devices, and multimedia environments—to name just a few.

There are three kinds of uses for technology in schools. First, teachers can design technology-based activities for their classrooms, for virtual learning environments, or for blended models using both in-class and virtual environments. Second, students can interact with technologies in a variety of ways, such as by using a computer or tablet to complete assignments or by collaborating in a virtual environment with other students or teachers using interactive cloud computing applications. Cloud computing allows computer users online access to applications such as Google documents or Microsoft Web Mail along with computing assets such as network-accessible data storage and processing. Finally, administrators use technology to track teacher, class, and student information in school, district, or statewide systems. You could be involved with any or all three of these uses of technology in your teaching. A golden rule for technology integration

in any classroom is that you do not need to reinvent the wheel. Focus on identifying centers of expertise where existing resources are available to adapt and build on.

VIRTUAL LEARNING ENVIRONMENTS. Virtual learning environments (VLEs) is a broad term that describes many ways of learning in virtual systems. The most traditional VLE is referred to as a **learning management system (LMS)**. LMSs deliver e-learning using applications such as Moodle, BlackBoard, RCampus, and D2L. LMSs are large, complex, and costly—my university uses a system we call “Carmen” to support every course on campus. My Carmen sites have readings, discussion groups, class-built wikis, PowerPoints, Weblinks, a calendar, and many other resources. We taught classes without these assets for decades, but the LMS has expanded our teaching and learning options. To deal with costs, some institutions use free *open-source software* to construct VLEs. Tools that support open-source software include Moodle, Google Apps, and PBWorks.

Betty's Brain is an example of a VLE developed by Vanderbilt and Stanford Universities (go to <http://www.vanderbilt.edu> and search betty's brain for more information). Using this computer-based system, students are challenged to “teach” a topic in science to a computer agent known as Betty. The system provides hypertext resources for the students to use in planning their instruction (and learning the concepts and processes under study). As I have discovered so many times in my life, the best way to learn something is to teach it. Remember, the research on cooperative learning shows that the *explainer* learns more than the listener (O'Donnell, 2006). Like all good teachers, the students who are working with Betty must keep track of how well she is learning—by asking Betty to answer questions and take quizzes. The computer system also includes an expert on the topic, Mr. Davis, who grades Betty's work and mentors the student “teachers.” See Figure 10.4 for an example screen from *Betty's Brain*.

PERSONAL LEARNING ENVIRONMENTS. There are different kinds of VLEs. A **personal learning environment (PLE)** framework provides tools that support individualized learning

FIGURE 10.4

BETTY'S BRAIN: A VIRTUAL LEARNING ENVIRONMENT

Betty's Brain is a computer-based learning environment that uses learning-by-teaching to engage students in learning about science topics.

Virtual learning environments (VLE) A broad term that describes many ways of learning in virtual or online systems.

Learning management system (LMS) Systems that deliver e-learning, provide tools and learning materials, keep records, administer assessments, and manage learning.

Personal learning environment (PLE) Provides tools that support individualized learning in a variety of contexts and situations.

in a variety of contexts and situations; the learners assume control of how and when their learning occurs. Students working in PLEs can download an assignment at a coffee shop, read the material on the bus, and then post an analysis on the discussion board at 4:00 A.M. from their room. Learning in PLEs can be asynchronous—taking place any time and anywhere. Complex PLEs include tools that assess learners' knowledge and then adapt the next content to fit their unique needs. Tools that support PLEs include computer-based training modules, e-books, cognitive tutors, quizzes, and self-assessment tools. Many have been very successful. For example, the intelligent tutoring system (ITS) *Cognitive Tutors* teaches mathematics in schools throughout the United States (Graesser, 2013). Math is one thing, but how about more ill-structured domains like writing? An ITS can help here, too. In one study with tenth graders, *Writing Pal* improved essay writing, although the students found some aspects of the system annoying (Roscoe & McNamara, 2013).

A **personal learning network (PLN)** is a framework in which knowledge is constructed through online peer interactions. PLNs consist of both synchronous (real-time) and asynchronous technologies using interactive Web conferencing, hybrid classes, or online discussions. A PLN can be used for K–12 instructional purposes and also as a resource for professional development. Social networking tools such as Facebook, Twitter, Edutopia, and EdWeb allow the instruction to move outside the school, city, and even country to include learners with similar interests around the globe. Tools that support PLNs include Web conferencing tools, such as Adobe Connect instant messaging, interactive video and audio messaging, social networking, discussion boards, and blogs.

IMMERSIVE VIRTUAL LEARNING ENVIRONMENTS. The most complex VLE is an **immersive virtual learning environment (IVLE)**. The IVLE is a simulation of a real-world environment. The purpose is to learn through enculturation, for example, by being eco explorers in the rainforest or reporters covering a story about an outbreak of food poisoning in a local school (Gee, 2008; Gibson, Aldrich, & Prensky, 2006; Shaffer et al., 2009). IVLEs are designed to be domain specific using realistic scenarios (Bagley & Shaffer, 2009; Shaffer et al., 2009). IVLE experiences mimic tasks required in a professional practicum, such as interviewing sources for a news story about food poisoning, following leads to identify the source of a problem, and crafting an accurate engaging article, thus blending real-world engagement in a virtual scenario. These immersive environments often include cognitive tutors; the technology is programmed to interact as a tutor by providing prompts after analyzing the student's response.

GAMES. What about educational games? Certainly students use games outside school. One estimate is that American students ages 8 to 18 spend an average of 13 hours a week playing video games—some more and some less, but some up to 30 hours a week. Often students are playing with others who may or may not be in the same room, or even time zone. Over 50% of adults also play video games—you may be one (Arena, 2015; Lenhart, 2015).

Many researchers suggest games provide a natural, engaging form of learning and that “combining games with educational objectives could not only trigger students' learning motivation, but also provide them with interactive learning opportunities” (Sung & Hwang, 2013, p. 44). Games might include a knowledge base developed by experts, a challenge to students in the form of a problem or role-play, and a final product such as creating a database, report, design, or problem solution. But as a teacher, you may not have access to well-designed video games that match or support your curriculum. How can you capitalize on students' extensive gaming outside school? One suggestion is to think of games as ways of “tilling the soil,” getting students ready for learning by developing prior knowledge (Arena, 2015). For example, *Motion Math: Pizza*, available from the iTunes App Store, gives students experience with the concept of supply and demand as they operate a pizza store. *Angry Birds* gives students experience with scientifically accurate trajectories of projectiles—a basis for learning about Newtonian physics. There are curricula that explore conservation of momentum, terminal velocity, and other subjects based on *Portal2* (go to the Teach with Portals Web site). Teachers have developed

Personal learning network (PLN) Framework in which knowledge is constructed through online peer interactions.

Immersive virtual learning environment (IVLE) A simulation of a real-world environment that immerses students in tasks like those required in a professional practicum.

semester-long projects based on the game series *Civilization*. To see other ideas, go to the Educade Web site. Even though not all your students will play the same games, you still can develop lessons around the games they do play. For example, a language arts teacher might assign a persuasive essay requiring each student to convince the rest of the class to play his or her favorite game. This means that student write based on personal expertise and motivation. See Arena (2015) for more ideas.

But even with this promise, there is no guarantee that students will learn from all educational games or transfer their learning to situations outside the game (Jabbar, & Felicia, 2015; Ownston, 2012; Roschelle, 2013). Pieter Wouters and his colleagues in the Netherlands (2013) analyzed 38 studies of serious educational computer games conducted from 1990 to 2012. They concluded that games were more effective than traditional instruction in terms of learning and retention, but not in terms of motivation, the one thing you might think would be an asset for games. Students participating in games learned more when the games were not the only method but were supplemented with other forms of instruction, when there were multiple sessions, and when the students worked in groups. In addition, based on a synthesis of research with K–12 students, Douglas Clark and his colleagues (2016) concluded games designed to enhance learning, particularly games that included scaffolding that adapted the game to students' individual needs and interests, were more effective than teaching approaches that did not include games.

Massive multi-player online games (MMOGs) are interactive gaming environments constructed in virtual worlds in which the learner assumes a character role of avatar. Many of these games have **affinity groups**—online communities that share knowledge, strategies, role-play scenarios, game modifications, or fan fiction stories and novels based on the games. These groups provide practice in problem solving, communication, reading, and writing. In fact, students who don't seem to be good readers in school can be very capable readers of even complex text when they are trying to improve their gaming skills—a goal that makes sense to them. The University of Wisconsin Casual Learning Lab is using the wildly popular *World of Warcraft* as part of an after-school learning program. See wowinschool.pbworks.com/ for some ideas (King, 2015).

Developmentally Appropriate Computer Activities for Young Children

Digital media are appealing, but are they appropriate for preschool children? This is a hotly debated issue. In making decisions about computers and young children, ask these four questions (Bullard, 2017):

- Is it the best tool for the job?
- Will it produce added value to the activity?
- Is the activity itself beneficial to the child?
- Are the benefits worth the costs?

Developmentally appropriate ways to use computers with 3- and 4-year-olds differ from the ways we use computers in kindergarten and the primary grades. Here are a few guidelines. Computers should not be used to do solitary drill-and-practice activities. Software for young children should include simple spoken directions; the activities should be open-ended and encourage discovery, exploration, problem solving, understanding of cause and effect, and social interaction. Children should be able to remain in control of the activities through a variety of responses. Finally, the content should be appropriate for and respectful of diverse cultures, ages, and abilities (M. A. Fischer & Gillespie, 2003; Frost, Wortham, & Reifel, 2012; Tsantis, Bewick, & Thouvenelle, 2003).

There is another important consideration: Do the program's multimedia features (e.g., embedded videos, zoom-ins, music, added sounds, images) add to learning or take away from it? One danger is that programs will include attractive visuals or sound effects that actually interrupt and interfere with the development of important concepts. For example, do the sounds of a buzz saw and the thud of a falling tree in a Peter Rabbit storytelling program foster distractibility and interfere with understanding the story, plot,

Massive multi-player online games (MMOG) Interactive gaming environments constructed in virtual worlds where the learner assumes a character role, or avatar.

Affinity groups Online communities for video game users where they can share knowledge, strategies, role-play scenarios, game modifications, or fan fiction stories and novels based on the games they are playing.

FIGURE 10.5

CHECKLIST FOR SELECTING APPROPRIATE SOFTWARE FOR YOUNG CHILDREN

When screening software, consider the following criteria:

- ☐ Does the software have high educational or informational value? Is value added by using the software? Or would this information be better presented in a different format?
- ☐ Is the software developmentally appropriate for the children using it? According to Haugland (2005), only 20% of software is appropriate for children. Beware of software that is just an electronic work sheet page. The age limit, educational objectives, and educational philosophy should be clearly stated (Peterson, Verenikina, & Herrington, 2008).
- ☐ Is the software designed so that the child can use it independently (simple and clear directions, uses speech when appropriate, uses picture menus, and organized for intuitive use) (Prairie, 2005)?
- ☐ If providing simulations, they are realistic and real-world (Peterson, Verenikina, & Herrington, 2008).
- ☐ Is the child able to exercise control when using the software (sets the pace, can repeat a process, can stop and resume, chooses from multiple paths, and frequently saves)?
- ☐ Does the software encourage active learning (requires active participation and encourages exploration and further investigation, allows for trial and error)?
- ☐ Is the software exciting and interesting (utilizes many senses including sound, music, and voice; includes graphics and sounds that are motivating for young children; and is relevant to the group of children using the software)?
- ☐ Does the software scaffold children's learning (provides increasing challenges and a variety of levels, provides nonthreatening feedback allowing children to know their progress, provides hints and instruction, and does not penalize for mistakes)?
- ☐ Is the software anti-bias, containing respectful images of diverse cultures, multiple languages, people of different ages, abilities, colors, and diverse family structures (NAEYC, 1996)?
- ☐ Does the software promote prosocial values (no violence or implicit violence is present such as "blowing it up" to get rid of mistakes) (Tsantis, Bewick, & Thouvenelle, 2003)?
- ☐ Is the software preselected to match curricular goals, and is the software tied closely to other curricular activities? Software should support or be supported by the curriculum.
- ☐ Does the software have high-quality graphics and sounds? Graphics and sound need to add to the quality rather than being distracting.
- ☐ Is the software accessible for children with special needs?
- ☐ Does the software provide delight, enchantment, and adventure such as opportunities for free exploration, finding hidden secrets, and elements of surprise (Plowman, McPake, & Stephen, 2012)?

and characters? Maybe (Tsantis et al., 2003). The bottom line is that multimedia elements should focus on meaning and not just provide attractive "bells and whistles." Figure 10.5 is a checklist for evaluating software for young children.

See the *Guidelines: Using Computers* for more ideas.

COMPUTATIONAL THINKING AND CODING. Using technology for learning and for life has become so pervasive for all ages that some educators argue students should

GUIDELINES

Using Computers

IF YOU HAVE ONLY ONE COMPUTER IN YOUR CLASSROOM

Provide convenient access.

Examples

1. Find a central location if the computer is used to display material for the class.
2. Find a spot on the side of the room that allows seating and view of the screen, but does not crowd or disturb other students if the computer is used as a workstation for individuals or small groups.

Be prepared.

Examples

1. Check to be sure software needed for a lesson or assignment is installed and working.
2. Make sure instructions for using the software or doing the assignment are in an obvious place and clear.
3. Provide a checklist for completing assignments.

Create “trained experts” to help with computers.

Examples

1. Train student experts, and rotate experts.
2. Use adult volunteers—parents, grandparents, aunts and uncles, older siblings—anyone who cares about the students.

Develop systems for using the computer.

Examples

1. Make up a schedule to ensure that all students have access to the computer and no students monopolize the time.
2. Create standard ways of saving student work.

IF YOU HAVE MORE THAN ONE COMPUTER IN YOUR CLASSROOM

Plan the arrangement of the computers to fit your instructional goals.

Examples

1. For cooperative groups, arrange so students can cluster around their group's computer.
2. For different projects at different computer stations, allow for easy rotation from station to station.

Experiment with other models for using computers.

Examples

1. Navigator Model—four students per computer: One student is the (mouse and keyboard) driver, another is the “navigator.” “Back-seat driver 1” manages the group's progress and “back-seat driver 2” serves as the timekeeper. The navigator attends a 10- to 20-minute training session in which the facilitator provides an

overview of the basics of particular software. Navigators cannot touch the mouse. Driver roles are rotated.

2. Facilitator Model—six students per computer: he facilitator has more experience, expertise, or training and serves as the guide or teacher.
3. Collaborative Group Model—seven students per computer: Each small group is responsible for creating some component of the whole group's final product. For example, one part of the group writes a report, another creates a map, and a third uses the computer to gather and graph census data.

NO MATTER HOW MANY COMPUTERS YOU HAVE IN YOUR CLASSROOM

Select developmentally appropriate programs that encourage learning, creativity, and social interaction.

Examples

1. Encourage two children to work together rather than having children work alone.
2. Check the implicit messages in programs. For example, some drawing programs allow children to “blow up” their projects if they don't like them, so instead of solving a problem, they just destroy it. Tsantis et al. (2003) recommend a recycle metaphor instead of a “blow it up” option.
3. Look for programs that encourage discovery, exploration, problem solving, and multiple responses.

Monitor children as they work at computers.

Examples

1. Make sure computers are in areas where adults can observe them.
2. Discuss with children why some programs or Web sites are off limits.
3. Balance computer time with active play such as hands-on projects, blocks, sand, water, and art.

Keep children safe as they work at computers.

Examples

1. Teach children to shield their identity on the Internet and monitor any “friends” they may be communicating with.
2. Install filtering software to protect children from inappropriate content.

Sources: Suggestions from Frost, J. L., Wortham, S. C., & Reifel, S. (2005). *Play and Child Development* (2nd ed.). Upper Saddle River, NJ: Prentice-Hall, pp. 76–80, and Tsantis, L. A., Bewick, C. J., & Thouvenelle, S. (2003, November). Examining Some Common Myths About Computer Use in the Early Years. *Beyond the Journal: Young Children on the Web* (pp. 1–9). Bullard, J. (2017). *Creating Environments for Learning: Birth to Age Eight* (3rd Ed.). Boston: Pearson, pp. 342–352.

learn **computational thinking**, defined as “knowing how to use data, models, simulations, and algorithmic thinking to formulate and solve problems” (Malby et al., 2017, p. 160), in other words, thinking like a computer scientist. According to the national K–12 Computer Science Standards, computational thinking is a skill that students should begin to develop in elementary school (<http://www.csteachers.org>).

Computational thinking includes, but is not limited to, programming and coding. Since the 1980s and 1990s when Seymore Papert (1980, 1991) introduced LOGO programming and turtle graphics for children, interest has grown in teaching students to code. Some educators claimed that programming teaches students to think logically in all areas, but others said programming just helped students learn to program. Even so, there is ongoing interest in and advocacy for the value of coding as a way to foster computational thinking. High school courses in computing are growing in popularity. For example, between 2010 and 2014, enrollment in computing courses increased by almost 800% (ECS, 2014). See the Exploring Computer Science Web site for ideas about curriculum (exploringcs.org).

Simple programing languages available today include Scratch, Alice, GameMaker, Kodable Pro, Cargo-Bot, Kodu, Daisy the Dinosaur, and Greenfoot. There is even a version of Scratch (developed by MIT) called Scratch Jr. that will allow children from kindergarten through second grade to program (Guernsey, 2013)! Many of these languages allow even very young students to build programs by snapping together images of blocks on the computer screen. The way the blocks snap together controls actions of different characters on the computer screen (Grover & Pea, 2013). Costumes, sounds, colors, and other effects can be added. Table 10.7 provides other resources for learning to code.

MEDIA/DIGITAL LITERACY. With the advent of digital media comes a new concern with literacy—media or digital literacy. Today, to be literate—to be able to read, write, and communicate—children have to read and write in many media, not just printed words. Films, videos, DVDs, computers, photographs, artwork, magazines, music, TV, billboards, and more communicate through images and sounds. How do children read these messages? This is a new area of research and application in educational and developmental psychology.

As an example of application, consider Project Look Sharp at Ithaca College, directed by Cynthia Scheibe, a developmental psychologist. The goal of the project is to provide materials, training, and support as teachers integrate media literacy and critical thinking about media into their class lessons. Teachers participating in the project help their students become critical readers of media. For example, during the 2016 U.S. Presidential election, Project Look Sharp provided 10 different lesson plans that helped students decode the candidates’ campaign ads, videos, Web sites, articles, and news releases on topics such as racial justice, national security, voting rights, economic inequality, climate change, and immigration. In the first lesson, students view one video ad from each

Computational thinking The thought processes involved in formulating problems so you can represent their solution steps and algorithms for computing.

candidate that depicts African American males. Students then decode the videos to determine each candidate's point of view on protecting African American rights and identify specific ways those attitudes are communicated in the videos.

Project Look Sharp suggests questions such as the following to guide discussion of media:

1. Who made—and who sponsored—this message, and why was it made? Who paid for it?
2. Who is the target audience, and how do you know?
3. What are the different techniques used, and why are they used?
4. What messages are communicated (and/or implied)? What is your interpretation, and why?
5. How current, accurate, and credible is the information in this message?
6. What is left out of the message that might be good to know?

The *Guidelines: Supporting the Development of Media Literacy* give more ideas from Scheibe and Rogow (2008) for supporting the development of media literacy in your students—a skill that seems more important than ever.

GUIDELINES

Supporting the Development of Media Literacy

Use media to practice general observation, critical thinking, analysis, perspective taking, and communication skills.

Examples

1. Ask students to think critically about the information presented in advertising, “news” programs, and textbooks. Would different people interpret the messages in differing ways?
2. Foster creativity and communication by having students produce their own media on a topic you are studying.
3. Ask students to compare ways information might be presented in a documentary, TV news report, advertisement, public service announcement, and so on.
4. Give examples of how word selection, background music, camera angles, color, and so on, can be used to set a mood or bias a message.

Use media to stimulate interest in a new topic.

Examples

1. Have students work in small groups to read, analyze, and discuss a controversial magazine, newspaper, or online article about the topic.
2. Ask students to do a media search for information about a topic.
3. Use a short video, magazine illustration, blog entry, or brief article to stimulate discussion, encouraging students to express what they already know or their opinion about a topic.

Help students identify what they already know or believe about a topic based on popular media content. Help them identify erroneous beliefs.

Examples

1. What do students “know” about space travel?

2. What have they learned about biology from advertisements?

Use media as a standard pedagogical tool.

Examples

1. Encourage students to follow (and write about) current events, including tracking a single story across diverse media sources.
2. Assign homework that makes use of different media.
3. Have students express opinions or attempt to persuade using different media, including photographs, collages, videos, poems, songs, animated films.

Analyze the effects that media had on historical events.

Examples

1. How were Native Americans portrayed in art and in films?
2. What sources of information were available 50 years ago? 100 years ago?

Use video effectively.

Examples

1. Show short segments, not whole films or programs.
2. Leave the lights on to encourage active viewing and discussion.
3. Before viewing, let students know what they should be looking/listening for.
4. Pause periodically during viewing to point out important information or ask questions.

For more ideas, see the Project Look Sharp Web site.

TRADITIONAL AND FLIPPED CLASSROOMS

	Traditional Classroom	Flipped Classroom
What happens during class	Teacher-led instruction with whole groups, small groups, and individuals	Student-led activities with whole groups, small groups, and individuals
	Students as learners	Students as teachers and learners
	Teacher comes ready to teach by imparting information or directing activities	Students come prepared to learn by doing activities and adding to online information
What happens outside of class	Students do homework using paper worksheets and writing prompts	Students watch videos or pencasts or listen to podcasts of teacher presentations
	Reading assignments come from paper textbooks	Reading assignments come from online textbooks or interactive web resources

Source: Maloy, R. W., Verock, R-E., Edwards, S. A., & Woolf, B. P. (2017). *Transforming Learning with New Technologies* (3rd ed.). Boston: Pearson, p. 42]

The Flipped Classroom

Some of you reading this book have viewed Salman Khan's TED talk about reinventing education. Khan founded a nonprofit educational organization that produces video tutorials on mathematics and many other subjects. If you haven't checked it out, I recommend you spend some time exploring the Khan Academy Web site. In his TED talk, Khan described one use of his tutorials—to "flip the classroom." In a flipped classroom what usually happens in class—lessons, lectures, note taking, worksheets, direct teaching—is moved outside class, and what usually happens at home—homework, projects, practice—happens in class under the teacher's supervision and support. This arrangement allows the individual student to learn at his or her own pace away from school, and transforms the classroom into a more dynamic and interactive group learning space where time can be spent reviewing and applying concepts studied at home, getting further teacher or peer explanation and scaffolding, and assessment with feedback. Invention and creativity should be encouraged.

It appears that teachers are listening. In 2014, 78% of teachers in a national survey reported that they had flipped at least one lesson and 45% said they flipped once or twice a week (Malby et al., 2017). What does a flipped classroom look like? Figure 10.6 gives some basics.

In many ways the flipped classroom is a good example of constructivist teaching. Teachers are no longer just providers of information. Students use teacher-produced worksheets, minilectures, and outlines as well as readings and other study tools to learn at home. If all the students have access to the Internet, other at-home learning activities can be added such as online resources, video tutorials, and collaborative discussions. In class, the teacher's role is changed to facilitator and scaffolder of learning. Groups can work on activities at their level, allowing teachers to differentiate instruction to students' needs. For students who do not have access to powerful learning technologies at home, some class time can be devoted to online research, learning games, wikis, blogs, creating digital portfolios, listening to or creating podcasts, or using learning apps. In college, whole courses might be flipped by putting all the lectures and readings online through Blackboard or Moodle, but in elementary or secondary schools, the teacher may just flip one lesson—doing assignments outside class to prepare for project-based activities in class, for example (Malby et al., 2017). Of course, to take advantage of the flipped classroom, students have to be self-disciplined to engage deeply with the lectures or PowerPoints at home and unsupervised.

▼ SUMMARY

Cognitive and Social Constructivism (pp. 410–415)

Describe two kinds of constructivism. Constructivism is more a *philosophy* about knowledge than a scientific theory of learning. *Cognitive* constructivists such as Piaget are concerned with how individuals make sense of their world, based on individual knowledge and beliefs. *Social* constructivists such as Vygotsky believe that social interaction, cultural tools, and activity shape individual development and learning. By participating in a broad range of activities with others, learners appropriate the outcomes produced by working together; they acquire new strategies and knowledge of their world.

In what ways do constructivist views differ about knowledge sources, accuracy, and generality? Constructivists debate whether knowledge is constructed by mapping external reality, by adapting and changing internal understandings, or by an interaction of external forces and internal understandings. Most psychologists believe there is a role for both internal and external factors, but differ in how much they emphasize one or the other. Also, there is discussion about whether knowledge can be constructed in one situation and applied to another or whether knowledge is situated—specific and tied to the context in which it was learned.

What is meant by thinking as enculturation? Enculturation is a broad and complex process of acquiring knowledge and understanding consistent with Vygotsky's theory of mediated learning. Just as our home culture taught us lessons about the use of language, the culture of a classroom can teach lessons about thinking by giving us models of good thinking; providing direct instruction in thinking processes; and encouraging practice of those thinking processes through interactions with others.

What are some common elements in most constructivist views of learning? Even though there is no single constructivist theory, many constructivist approaches recommend complex, challenging learning environments and authentic tasks; social negotiation and co-construction; multiple perspectives and representations of content; understanding that knowledge is constructed; and student ownership of learning.

Designing Constructivist Learning Environments (pp. 415–426)

What are some basic assumptions to guide the design of learning environments? Key assumptions to guide design are that experts develop deep conceptual knowledge, learning comes from the learner, creating learning environments is the responsibility of the school, students' prior knowledge is key, and reflection is a critical component of learning. These common assumptions enable researchers from a variety of disciplines to address the same issues of learning from a variety of perspectives.

What is scaffolding? Scaffolding involves making connections between teachers' cultural knowledge and the everyday experience and knowledge of the student by providing supports for learning—prompts, cues, needed information, coaching, and so on. Scaffolding includes both *motivational* and *cognitive* support—helping students stay engaged and interested while also helping them move toward deeper

learning. Motivational support includes supports such as connecting to student interests, redirecting attention, and coping with frustration. Cognitive supports include tailoring instruction, fading supports, and gradually transferring responsibility to students.

How can teachers facilitate using advance organizers and deep questioning? Advance organizers facilitate instruction by providing introductory material broad enough to encompass all the information that will follow. The organizers can serve three purposes: They direct your attention to what is important in the upcoming material, they highlight relationships among ideas that will be presented, and they remind you of relevant information you already have. Teachers also can facilitate learning by training students in how to ask and answer deep questions when they read, listen to a lecture, or participate in class discussions. These questions prompt students to reason about underlying principles and big ideas in the content, make reasoned arguments, and provide evidence.

Distinguish between inquiry methods and problem-based learning. The inquiry strategy begins when the teacher presents a puzzling event, question, or problem. The students ask questions (only yes–no questions in some kinds of inquiry) and then formulate hypotheses to explain the event or solve the problem; collect data to test the hypotheses about causal relationships; form conclusions and generalizations; and reflect on the original problem and the thinking processes needed to solve it. Problem-based learning may follow a similar path, but the learning begins with an authentic problem—one that matters to the students. The goal is to learn math or science or history or some other important subject while seeking a real solution to a real problem.

Describe six features that most cognitive apprenticeship approaches share. Students observe an expert (usually the teacher) model the performance; get external support through coaching or tutoring; and receive conceptual scaffolding, which is then gradually faded as the students become more competent and proficient. Students continually articulate their knowledge—putting into words their understanding of the processes and content being learned. They reflect on their progress, comparing their problem solving to an expert's performance and to their own earlier performances. Finally, students explore new ways to apply what they are learning—ways that they have not practiced at the master's side.

Describe the use of dialogue in reciprocal teaching. The goal of reciprocal teaching is to help students understand and think deeply about what they read. To accomplish this goal, students in small reading groups learn four strategies: summarizing the content of a passage, asking a question about the central point, clarifying the difficult parts of the material, and predicting what will come next. These strategies are practiced in a classroom dialogue about the readings. Teachers first take a central role, but as the discussion progresses, the students take more and more control.

Collaboration and Cooperation (pp. 426–437)

What are the differences between collaboration and cooperation? One view is that collaboration is a philosophy about how to relate to others—how to learn and work. Collaboration is a way of dealing with people that respects differences, shares authority, and builds on the knowledge that is distributed among other people. Cooperation, on the other hand, is a way of working together with others to attain a shared goal.

Describe five elements that define true cooperative learning. Promotive interaction means that group members encourage and facilitate each other's efforts. They usually interact face-to-face and close together, but they also could interact via digital media around the world. Group members experience positive interdependence; they need each other for support, explanations, and guidance. Even though they work together and help each other, members of the group must ultimately demonstrate learning on their own. They are held individually accountable for learning, often through individual tests or other assessments. If necessary, the collaborative skills important for effective group functioning, such as giving constructive feedback, reaching consensus, and involving every member, are taught and practiced before the groups tackle a learning task. Finally, members monitor group processes and relationships to make sure the group is working effectively and to learn about the dynamics of groups.

What are the learning theory underpinnings of cooperative learning and what can go wrong? Learning can be enhanced in cooperative groups through rehearsal and elaboration (information processing theories), creation and resolution of disequilibrium (Piaget's theory), or scaffolding of higher mental processes (Vygotsky's theory). But if there is pressure in a group for conformity—perhaps because rewards are being misused or one student dominates the others—interactions can be unproductive and unreflective. Without feedback about accuracy, misconceptions might be reinforced, or the worst, not the best, ideas may be combined to construct a superficial or even incorrect understanding. Students who work in groups but arrive at wrong answers may be more confident that they are right. Also, the ideas of low-status students may be ignored or even ridiculed while the contributions of high-status students are accepted and reinforced, regardless of the merit of either set of ideas.

How should tasks match design in cooperative learning? Teachers have a role before, during, and after cooperative learning. First, they must select an appropriate task. A relatively structured task works well with a structured technique; extrinsic rewards can enhance motivation, effort, and persistence under these conditions; roles, especially those that focus attention on the work to be accomplished, also may be productive. On the other hand, strategies that encourage extended and productive interactions are appropriate when the goal is to develop higher-order thinking and problem solving. The use of rewards may well divert the group away from the goal of in-depth cognitive processing. When the goal of peer learning is enhanced social skills or increased intergroup understanding and appreciation of diversity, the assignment of specific roles and functions within the group might support communication. Rewards probably are not necessary and may actually get in the way because the goal is to build community, a sense of respect, and responsibility for team members.

What are some possible strategies for cooperative learning? Strategies include reciprocal questioning, Jigsaw, constructive/

structured controversy, and many cooperative structures described by Spencer Kagan. But cooperative learning is not for everyone. Sometimes students with learning disabilities and students with more advanced knowledge do not benefit from cooperative learning.

What are some dilemmas of constructivist practice? The first is conceptual: How do I make sense of cognitive versus social conceptions of constructivism and reconcile these different perspectives with my practice? The second dilemma is pedagogical: How do I teach in truly constructivist ways that both honor my students' attempts to think for themselves, but still ensure that they learn the academic material? Third are cultural dilemmas: What activities, cultural knowledge, and ways of talking will build a community in a diverse classroom? Finally, there are political dilemmas: How can I teach for deep understanding and critical thinking, but still satisfy the accountability demands of parents and the requirements of state achievement testing?

Designing Learning Environments in a Digital World (pp. 438–446)

What are some possible uses of technology in education? Technology such as computers, iPads, tablets, smart phones, digital readers, and interactive gaming systems are extremely popular among young people. In education, virtual learning environment (VLE) is a broad term that describes many ways of learning in virtual systems. There are different kinds of VLEs. The most traditional VLE is referred to as a learning management system (LMS). LMSs deliver e-learning using applications such as Moodle and BlackBoard. A personal learning environment (PLE) framework provides tools that support individualized learning in a variety of contexts and situations; the learners assume control of how and when their learning occurs. A personal learning network (PLN) is a framework in which knowledge is constructed through online peer interactions. The most complex VLE is an immersive virtual learning environment (IVLE). The IVLE is a simulation of a real-world environment where students work alone or with others to solve problems, create projects, simulate the skills of experts, visit historical sites, tour world-class museums, or play games that teach and apply academic skills. Technology by itself will not guarantee improvement in academic achievement; like any tool, technology must be used well by confident, competent teachers. Some educators are suggesting that all students should learn computational thinking—thinking like a computer scientist—to formulate and solve problems that can be solved using the computational processes like those applied by computers. Many systems allow even very young students to create computer programs. Also, every student should learn to critically evaluate all the digital media that bombards us today.

What is a flipped classroom? One possibility for using technology is the flipped classroom. In a flipped classroom, what usually happens in class—lessons, lectures, note taking, worksheets, direct teaching—is moved outside class, and what usually happens at home—homework, projects, practice—happens in class under the teacher's supervision and support. For students who do not have access to powerful learning technologies at home, some class time can be devoted to online research, learning games, wikis, blogs, creating digital portfolios, listening to or creating podcasts, or using learning apps.

MULTIPLE-CHOICE QUESTIONS

- Scholars have different views on how knowledge is constructed and acquired. Which of the following is NOT one of the widely accepted views?
 - Knowledge is acquired by constructing a representation of the outside world, either via direct teaching, feedback, and/or explanation.
 - Knowledge is acquired by transforming and (re-)organizing previous knowledge, which is more important than direct teaching.
 - Knowledge is acquired by mirroring immediate caregivers, such that more knowledgeable and attentive caregivers lead to more effective learning.
 - Knowledge is acquired from social interaction and experience. Any knowledge obtained from the outside world will be filtered by our culture, beliefs, and interaction with others.
- In Mrs. Shalini's classroom, students are engaged in learning the importance of healthy diet. She first introduced the key concepts of healthy eating, and then read the first chapter on the topic with the students. She later demonstrated how to summarize the reading, to ask example questions, to clarify key ideas, and to predict upcoming content. Second chapter onward, Mrs. Shalini progressively stepped out of the primary teaching role, and encouraged students to lead the discussion. Which type of learning is this an example of?
 - Reciprocal teaching
 - Problem-based learning
 - Cooperative learning
 - Jigsaw classroom
- Group learning comes with several disadvantages. Which of the following is NOT one of them?
 - Students typically find group learning less desirable than learning directly from teachers. Since motivation runs low, learning suffers.
 - Groups can induce conformity, such that everyone agrees on mainstream ideas without challenging them, leading to unproductive and unreflective learning.
 - Status differences within a group make an impact, such that opinions from high-status students are valued more than low-status students, regardless of merit of ideas.

D. Students may tend to socialize and distract themselves in group learning, leading to ineffective learning outcomes.

- Monica wanted to incorporate technological tools in her classroom to promote learning. She started by uploading teaching materials online and had students download them prior to coming to class. She also set up a discussion forum on Blackboard so that her students could engage in fruitful intellectual exchanges after class. Which of the following best describes Monica's technological use?
 - Learning Management System
 - Personal Learning Environment
 - Immersive Learning Environment
 - Flipped Classroom

CONSTRUCTED-RESPONSE QUESTIONS

Case

Joey was working on a course design for her social science class in the upcoming semester. Instead of having students complete multiple, smaller individual assignments throughout the semester, she wanted to put students into collaborative groups to work on a semester-long research project that would count towards a major portion of their grade. She wanted each group of students to select a research topic, to choose an appropriate study design for that topic, to conduct preliminary analysis and discussion, and, finally, to present their findings to the rest of the class at the end of the semester.

- Joey was unsure about the appropriate group size for her student groups. She wondered whether or not she should put students of different genders and cultures together. She also toyed with the idea of assigning the role of team lead to a student in each group. Discuss your suggestions for Joey on each of these counts.
- Consider Jigsaw classroom and Constructive/Structured controversies strategies. Which do you think would be a better option for Joey's classroom, and why?

▼ WHAT WOULD THEY DO?

TEACHERS' CASEBOOK Learning to Cooperate

Here is how some practicing teachers responded to the situation described at the beginning of the chapter about the class that hated cooperative learning.

PAULA COLEMER • *Special Education Teacher—English, History*

McClintock High School, Tempe, AZ

First, cooperative learning should be introduced early in the year and used in a variety of ways. Simple activities such as “think-pair-share” or “tell partner two things you learned” are basic ways of having students learn cooperatively. In addition, Socratic seminars are a great way to get students to dialogue together and gain deeper understanding of a concept. A Socratic seminar begins with the facilitator posing an open-ended question to the group. Participants are encouraged to learn through a meaningful discussion rather than memorizing bits of information. This takes practice, but if introduced early and practiced throughout the year, students will gain higher-level thinking skills. Finally, when having students do a team activity in class, groups need to be placed together thoughtfully and deliberately by the teacher. Team members need to be taught skills necessary for successful group work such as active listening and how to give and receive constructive criticism. Groups should have a variety of abilities, and students should be assigned specific tasks within the group so everyone has a role and purpose.

PAUL DRAGIN • *ESL Teacher, Grades 9–12*

Columbus East High School, Columbus, OH

To introduce cooperative learning, I will begin with some exercises that require no talking, such as puzzles that can only be completed by group cooperation and sharing without any verbal communication. Each group member receives pieces that make up a puzzle; the catch is that some of the pieces belong to another group member's puzzle. By trading pieces strategically and rapidly, the goal is to be the first group to complete all puzzles. This sets the stage for a discussion about the need to work together, because each person in the group needs something that another team member has in order to complete his or her puzzle. All effective cooperative learning requires the input of each member, and without that input, the activity has no chance of reaching its full potential. The establishment of groups is open to myriad options, and this is a good thing. Randomly assigning students as well as strategically assigning students to work together is an important learning opportunity for each student and better mimics real-world situations where we don't get to choose our coworkers.

JENNIFER PINCOSKI • *Learning Resource Teacher, K–12*

Lee County School District, Fort Myers, FL

To have effective groups, students need to respect each other and feel accepted by their peers. Therefore, it is important to incorporate some class-building and team-building exercises before the groups jump into academic content. The purpose of these activities is to acquaint students with one another and create a sense of community.

It will be easier to establish groups if the teacher collects information about the students first. This information can include anything from preferred learning style to favorite subject to career aspirations. It is also important to understand the students' levels of academic proficiency. Groups should be fluid, because different types of groups will accomplish different outcomes.

Teachers need to identify the objectives of an activity before creating the groups for that activity. In some situations, it might be appropriate to group students who are strong in a skill with students who have deficits in that skill. In other cases, it might be more effective to group together students with similar interests or career goals. It is up to the teacher to determine which type of group will result in the most worthwhile outcome for students.

LINDA SPARKS • *First-Grade Teacher*

John F. Kennedy School, Billerica, MA

I have used cooperative learning groups a lot through the years. There are so many things that can be learned and shared from working together. There is always frustration with some students, but overall it seems to work. I also try to set it up in a variety of ways, from letting them select their own groups, picking names out of a hat, and passing out different topics and forming groups based on the topics. I will use assessments to organize a group as well as make sure that each student has a specific task. (Project editor, information manager, organizer, reporter, researcher, etc.) There always seems to be one student ready to take a back seat and let the others in the group do all of the work. We go over the social skills needed to work in a group. We often will post a list in the classroom of simple rules: using appropriate language, speaking quietly and respectfully while working, listening and encouraging team members, and asking for help when needed. While they work in their groups, I will walk around the class and take notes on what is being worked on. I want to make sure there are no misconceptions about the project. After the project is completed, I grade them in a variety of ways. I give a grade to each participant for his/her contribution to the project, a group grade for the project and/or presentation, and a grade for group participation for the project. Students learn more when they are directly involved in what is being taught. This is yet another style of learning.

chapter eleven

SOCIAL COGNITIVE VIEWS OF LEARNING AND MOTIVATION

TEACHERS' CASEBOOK: Failure to Self-Regulate

You know that your students need to be organized and self-regulating to do well in both their current and their future classes. But many of the students just don't seem to know how to take charge of their own learning. They have trouble completing larger projects—many wait until the last minute. They can't organize their work or decide what is most important. Some can't even keep up with assignments. Their book bags are disaster areas—filled with long overdue assignment sheets and class handouts from last semester crumbled in with school newsletters and permission slips for field trips. You are concerned because they will need to be much more organized and on top of their work as they progress through their education. You have so much material to cover to meet district guidelines, but many of your students are drowning in the amount of work they already have.

CRITICAL THINKING

- Which organizational skills do students need to be successful in your subject or class?
- What could you do to teach these skills, while still covering the material that will be on the proficiency or achievement tests the students will have to take in the spring?
- How would you help students develop an authentic sense of efficacy for guiding their own learning?

WHAT WOULD YOU DO?

Tanor/Shutterstock

OVERVIEW AND OBJECTIVES

In the past four chapters, we analyzed different aspects of learning. We considered behavioral and information processing explanations of what and how people learn. We examined complex cognitive processes such as concept learning and problem solving. These explanations of learning focus on the individual and what is happening in his or her “head.” Recent perspectives have called attention to two other aspects of learning that are critical: social and cultural factors. In the previous chapter, we examined psychological and social constructivism. In this chapter, we look at social cognitive theory—a current view of learning and motivation that discusses dynamic interactions among many of the behavioral, personal, and environmental (including social and cultural) factors involved in learning and motivation.

Social cognitive theory has its roots in Bandura’s (1977, 1986) early criticisms of behavioral views of learning, as you read in Chapter 7. Social cognitive theory moved beyond behaviorism to focus on humans as self-directed agents who make choices and marshal resources to reach goals. Concepts such as self-efficacy, agency, and self-regulated learning are key in social cognitive theories. These concepts are important in understanding motivation as well, so this chapter provides a good path from learning to the discussion of motivation in the next chapter. We end the chapter with a look back at our tour through different models of instruction. Rather than debating the merits of each approach, we will consider the contributions of these different models of instruction, grounded in different theories of learning. Don’t feel that you must choose the “best” approach—there is no such thing. Even though theorists argue about which model is best, excellent teachers don’t debate. They apply all the approaches, using each one when appropriate.

By the time you have completed this chapter, you should be able to:

- Objective 11.1 Distinguish between social learning theory and social cognitive theory, including an explanation of triadic reciprocal causality.
- Objective 11.2 Discuss the roles of observation and modeling in learning, including factors that support learning by observation.
- Objective 11.3 Define self-efficacy and agency, distinguish these concepts from self-concept and self-esteem, explain the sources of self-efficacy, and discuss self-efficacy for teaching.
- Objective 11.4 Describe important components of self-regulated learning.
- Objective 11.5 Apply your knowledge to teach for self-efficacy and self-regulated learning.
- Objective 11.6 Explain the meaning and different applications of four basic theories of learning.

Bringing It All Together: Theories of Learning

Summary and Key Terms

Teachers' Casebook—Failure to Self-Regulate: What Would They Do?

SOCIAL COGNITIVE THEORY

Most of what is known today as *social cognitive theory* is based on the work begun by Albert Bandura in the 1950s at Stanford University. Before we talk about the theory, let's meet the man.

A Self-Directed Life: Albert Bandura

Albert Bandura's life story should be a movie. You could say he lived the American dream, except that he is from Canada. His parents were immigrants from Central Europe; they chose the rugged land of northern Alberta for their family farm. Bandura's parents never went to school, but they valued education. His father taught himself to read in three languages, giving young Albert a great model of self-regulated learning—a concept that figures prominently in social cognitive theory today. While attending high school, Bandura worked many jobs, including a stint as a carpenter at a furniture factory and one as a road worker on the Alaska Highway in the Yukon. He finished his undergraduate degree at the University of British Columbia in 3 years, even though he had to cram all his classes into the morning to have time for his afternoon jobs. Because he needed a morning class to fill one time slot, he enrolled in introductory psychology and found his future profession (Bandura, 2007, p. 46). His next stop was graduate school at the epicenter of psychological research in 1950—the University of Iowa. After earning his PhD (in 3 years again), Bandura joined the faculty at Stanford in 1953—he was 28 years old. More than 65 years later, he is the David Starr Jordan Professor of Social Science in Psychology/Emeritus at Stanford and has taught some of the children of his former students.

When I read Bandura's autobiography I was struck by how much his theories reflected his life as a self-directed, self-regulating learner growing up in a challenging environment. Describing his experiences in his two-teacher high school, Bandura (2007) said:

We had to take charge of our own learning. Self-directed learning was an essential means of academic self-development, not a theoretical abstraction. The paucity of educational resources turned out to be an enabling factor that has served me well rather than an insurmountable handicapping one. The content of courses is perishable, but self-regulatory skills have lasting functional value whatever the pursuit might be. (p. 45)

In the next sections we will look at the key features of Albert Bandura's work and social cognitive theory by considering four topics: moving beyond behaviorism, the

concept of triadic reciprocal causality, the power of observational learning, and the key function of self-efficacy in the development of human agency.

Beyond Behaviorism

Bandura believed basic behavioral principles were correct as far as they went, but also too limited to explain complex human thinking and learning. In his autobiography, Bandura (2007) describes the shortcomings of behaviorism and the need to put people in social context:

I found this behavioristic theorizing discordant with the obvious social reality that much of what we learn is through the power of social modeling. I could not imagine a culture in which its language; mores; familial customs and practices; occupational competencies; and educational, religious, and political practices were gradually shaped in each new member by rewarding and punishing consequences of their trial-and-error performances. (p. 55)

As you learned in Chapter 7, Bandura's early **social learning theory** included *enactive learning* (learning through reinforcement and punishment of your *own behaviors*) and added *observational learning*, that is learning through modeling and *observing others*. A formal definition for **modeling** is changes in behavior, thinking, or emotions that happen through observing another person (a model) being reinforced or punished for particular behaviors. Over time, Bandura's explanations of learning included more attention to cognitive (personal) factors such as *expectations* and *beliefs* in addition to the social influences of models (Bandura, 1986, 1997, 2001, 2016). His current perspective, **social cognitive theory**, retains an emphasis on the role of other people serving as models and teachers (the *social* part of social cognitive theory), but includes thinking, believing, expecting, anticipating, self-regulating, and making comparisons and judgments (the *cognitive* part). Social cognitive theory is a *dynamic system* that explains human adaptation, learning, and motivation. The theory addresses how people develop social, emotional, cognitive, and behavioral capabilities; how people regulate their own lives; and what motivates them (Bandura, 2007; Bandura & Locke, 2003). Many of the concepts from this chapter will help you understand motivation in Chapter 12.

Triadic Reciprocal Causality

I claimed earlier that social cognitive theory describes a system. This system, called **triadic reciprocal causality**, is the dynamic interplay among three kinds of influences: personal, environmental, and behavioral, as shown in Figure 11.1 on the next page. Personal factors (beliefs, expectations, cognitive abilities, motivation, attitudes, and knowledge), the physical and social environment (resources, consequences of actions, other people, models and teachers, and physical settings), and behavior (individual actions, choices, and verbal statements) all influence and are influenced by each other.

Figure 11.1 on the next page shows the interaction of person, environment, and behavior in learning settings (Pajares & Usher, 2008; Schunk, Meece, & Pintrich, 2014). External factors such as models, instructional strategies, classroom environments, or teacher feedback (elements of the environment for students) can affect student personal factors such as goals, sense of efficacy for the task (described in the next section), attributions (beliefs about causes for success and failure), expectations, and self-regulatory processes such as planning, monitoring, and controlling distractions. For example, teacher feedback can lead students to feel either more confident or more discouraged, and then the students adjust their goals accordingly. Environmental factors, such as rewards for turning in homework, and personal factors, such as setting challenging goals, can in turn encourage useful behaviors like effort and persistence that lead to successful learning (Usher & Schunk, 2017). But these behaviors also reciprocally influence personal factors. For example, as students achieve through increased effort (behavior), their self-efficacy and interest (personal factors) are likely to increase. Finally, student behaviors also affect their environment. For example, if students do not persist or if they perform poorly on assignments, teachers may change instructional strategies or learning group assignments, thus changing the learning environment for the students.

Think for a minute about the power of triadic reciprocal causality in classrooms. If personal factors, behaviors, and the environment are in constant interaction, then cycles of events are progressive and self-perpetuating. Suppose a student had difficulties in his previous school. The first day at his new school he is late to class because he got lost in the unfamiliar building. The student has a tattoo and several visible pierced body parts. He is anxious about his first day and hopes to do better at this new school, but the teacher's initial reaction to his late entry and dramatic appearance is a bit hostile. The

MyLab Education Video Example 11.1

In this video, students begin the school day with their usual classroom routine. The teacher sees one student working diligently on her assignment right after she arrives, and he reinforces her behavior with a slip of paper and a compliment. Consider how this type of reward might influence other students to model her behavior.

Social learning theory

Theory that emphasizes learning through observation of others.

Modeling Changes in behavior, thinking, or emotions that happen through observing another person—a model.

Social cognitive theory

Theory that adds concern with cognitive factors such as beliefs, self-perceptions, and expectations to social learning theory.

Triadic reciprocal causality

An explanation of behavior that emphasizes the mutual effects of the individual and the environment on each other.

FIGURE 11.1

A SOCIAL COGNITIVE VIEW OF RECIPROCAL INFLUENCES IN LEARNING

All three forces—personal, social/environmental, and behavioral—are in constant interaction. They influence and are influenced by each other.

Source: From "Social-Self Interaction and Achievement Behavior" by D. H. Schunk, 1999, *Educational Psychologist*, 34, p. 221. Adapted with permission of Lawrence Erlbaum Associates, Inc. and the author.

student feels insulted and responds in kind, so the teacher begins to form expectations about him and becomes more vigilant, less trusting. The student senses the distrust. He decides that this school will be just as worthless as his previous one—and wonders why he should bother to try. The teacher sees the student's disengagement, invests less effort in teaching him, and the cycle continues. These reciprocal effects are more than hypothetical. When Trevor and Kitty Williams (2010) examined data on high school students' confidence and achievement in mathematics in 30 different countries, they found evidence that math confidence and math achievement reciprocally influenced each other in 26 of the countries, just as Bandura would predict. You can see that if teachers' expectations are communicated to students (see Chapter 12), and these expectations affect students' confidence, then achievement can be influenced as well. In other words, the beliefs and behaviors of one person can create the environment for another!

Let's look more closely at two key elements of social cognitive theory: observational learning and self-efficacy. As we examine each of these more closely, we emphasize their implications for teaching.

MyLab Education [Self-Check 11.1](#)

MODELING: LEARNING BY OBSERVING OTHERS

What causes an individual to learn and perform modeled behaviors and skills? Several factors play a role. First, the developmental level of the observer makes a difference in learning. As children grow older, they can focus attention for longer periods of time, more effectively identify the important elements of a model's behavior to observe, use memory strategies to retain information, and motivate themselves to practice, as you can see in Table 11.1. A second influence is the status of the model. Children are motivated to imitate the actions of others who seem competent, powerful, prestigious, and enthusiastic, so parents, teachers, older siblings, athletes, action heroes, rock stars, or film personalities may serve as models, depending on the age and interests of the child.

Third, by watching others who are similar to us, we learn about what behaviors are appropriate and we are able to identify the range of behaviors we probably could accomplish (Schunk et al., 2014). Children and adolescents pay close attention to models they perceive to be similar in age, gender, or race. (When you watch your favorite show, do you pay closer attention to characters who seem similar to you?) All students need to see successful, capable models who look and sound like them, no matter what their ethnicity, socioeconomic status, or gender. Bandura (2016) describes Indian, African, Mexican, and Chinese television novellas and radio programs (like our reality shows) whose main characters deal effectively with social problems such as HIV prevention, women's rights, and overpopulation. Viewers' and listeners' behaviors and beliefs change after exposure to these stories. How?

MyLab Education
Video Example 11.2

This teacher models “how to think” as she demonstrates a think-aloud strategy for her students. By modeling, she hopes her students will be able to perform the same skill and use think-aloud to make predictions as they read.

TABLE 11.1 • Factors That Affect Observational Learning

CHARACTERISTIC	EFFECTS ON MODELING PROCESS
Developmental Status	Improvements with development include longer attention span and increased capacity to process information, use strategies, compare performances with memorial representations, and adopt intrinsic motivators.
Model Prestige and Competence	Observers pay greater attention to competent, high-status models. Consequences of modeled behaviors convey information about functional value. Observers attempt to learn actions they believe they will need to perform.
Vicarious Consequences	Consequences to models convey information about behavioral appropriateness and likely outcomes of actions. Valued consequences motivate observers. Similarity in attributes or competence signals appropriateness and heightens motivation.
Outcome Expectations	Observers are more likely to perform modeled actions they believe are appropriate, attainable, and will result in rewarding outcomes.
Goal Setting	Observers are likely to attend to models who demonstrate behaviors that help observers attain goals.
Self-efficacy	Observers attend to models when they believe they are capable of learning or performing the modeled behavior. Observation of similar models affects self-efficacy (“If they can do it, I can too”).

Source: From Schunk, D. H. (2016). *Learning Theories: An Educational Perspective* (7th ed.), p. 131. Reprinted by permission of Pearson Education, Inc., Upper Saddle River, NJ.

Look back at Table 11.1 for the answer: The factors related to how people *learn* from models involve goals, consequences, and expectations. If observers expect that certain actions of models will lead to particular outcomes (e.g., specific practice regimens leading to improved athletic performance) and the observers value those outcomes or goals, then the observers will pay attention to the models and try to reproduce their behaviors. Finally, observers are more likely to learn from models if the observers have a high level of self-efficacy—if they believe they are capable of doing the actions needed to reach the goals, or at least of learning how to do them (Bandura, 1997; Schunk et al., 2014). Of course, this works both ways. Watching another person perform a skill successfully can also increase the observers' beliefs that they can do it too. We'll examine this more later.

Elements of Observational Learning

STOP & THINK Your interview for a position in the middle school is going well. Now you are asked, "Who are your role models as teachers? Do you hear yourself saying or see yourself doing things that other teachers from your past have done? Are there teachers from films or books that you would like to emulate?" •

Through observational learning, we discover not only *how* to perform a behavior but also what will happen to us in specific situations if we perform it. Observation can be a very efficient learning process. The first time children hold hairbrushes, cups, or baseball bats, they usually brush, drink, or swing as well as they can, given their current muscle development and coordination. Through comparison with a model, we also can identify adjustments that may produce better outcomes. To learn new behaviors or refine current abilities, Bandura (1986) proposed that four elements of observational learning are essential: paying attention, retaining information or impressions, producing behaviors, and being motivated to repeat the behaviors.

ATTENTION. To learn through observation, we have to pay attention. This includes both selective attention (paying attention to the correct cues and information) as well as sustained attention (maintaining focus). In teaching, you will have to ensure students' attention to the critical features of the lesson by making clear presentations and highlighting important points. In demonstrating a skill (for example, threading a sewing machine, performing a dissection, or operating a lathe), you may need to have students look over your shoulder as you work. Seeing your hands from the same perspective as they see their own directs their attention to the right features of the situation and makes observational learning easier.

RETENTION. To imitate the behavior of a model, you have to remember each step. This involves mentally representing the model's actions in some way, probably as verbal steps ("Hwa-Rang, the eighth form in Tae Kwan Do karate, is a palm-heel block, then a middle riding stance punch, then ..."), or as visual images, or both. Retention can be improved by mental rehearsal (imagining imitating the behavior) or by actual practice. In the retention phase of observational learning, practice helps us remember the elements of the desired behavior, such as the sequence of steps.

PRODUCTION. Once we "know" how a behavior should look and remember the elements or steps, we still may not perform it smoothly without a great deal of practice, feedback, and coaching about subtle points. In the production phase, practice makes the behavior smoother and more expert. Of course, if a child does not have the physical or developmental skills needed to produce the behavior, even extensive practice and feedback may not be enough. The ideal conditions for practice toward expert production will typically involve some form of feedback that compares the learner's performance to that of the model (e.g., specific teacher feedback, explicit coaching, reviewing video of the performance, deliberate practice of the weak parts).

MOTIVATION AND REINFORCEMENT. Social cognitive theory distinguishes between acquisition and performance. We may acquire a new skill or behavior through observation, but we may not perform that behavior until we have some motivation or incentive to do so. Reinforcement can play several roles in observational learning. If we anticipate being reinforced for imitating the actions of a model, we may be more motivated to pay attention, remember, and reproduce the behaviors. In addition, reinforcement is important in maintaining learning through persistence. Without some kind of reinforcing consequence, new behaviors will likely disappear (Schunk, 2016). For example, if an unpopular student adopted the dress of the “in” group, but was ignored or ridiculed, it is unlikely that the imitation would continue. Similarly, learning new academic tasks is usually accompanied by some failure—and reinforcement for progressive gains helps learners maintain focus on their growth rather than on their current struggles.

Bandura identifies three forms of reinforcement that can encourage observational learning. First, of course, the observer may reproduce the behaviors of the model and receive **direct reinforcement**, as when a gymnast successfully executes a front flip/round-off combination and the coach/model says, “Excellent!”

But the reinforcement need not be direct—it may be **vicarious reinforcement**. The observer may simply see others reinforced for a particular behavior and then increase his or her production of that behavior. For example, if you compliment two students on the attractive illustrations in their lab reports, several other students who observe your compliments may turn in illustrated lab reports next time. Most TV ads hope for this kind of effect. People in commercials become deliriously happy when they drive a particular car or drink a specific energy drink, and the viewer is supposed to do the same; the viewer’s behavior is reinforced vicariously by the actors’ obvious pleasure. Punishment can also be vicarious: You may slow down on a stretch of highway after seeing several people get speeding tickets there. A student may curb her comments on Facebook after seeing a friend teased for making a similar post.

The final form of reinforcement is **self-reinforcement**, or controlling your own reinforcers—one aspect of *self-regulation* described later in this chapter. Self-reinforcers may be intrinsic (e.g., feelings of satisfaction at a job well-done) or extrinsic (e.g., rewarding yourself with a special treat after accomplishing a goal). If one goal of education is to produce people who are capable of educating themselves, then students must learn to manage their own lives, set their own goals, and provide their own reinforcement. In adult life, rewards are sometimes vague and goals often take a long time to reach. Think about how many small steps are required to complete an education and find your first job. In teaching, sometimes self-reinforcement is all that keeps you going in the face of difficult students and demanding parents. Life is filled with tasks that call for this sort of self-regulation (Rachlin, 2004).

Social cognitive theory has some powerful implications for teaching. In this section, we will look more closely at using observational learning in teaching.

Observational Learning in Teaching

STOP & THINK How would you incorporate observational learning into your teaching? What are the skills, attitudes, and strategies that can be modeled in teaching your subject? •

We have explored how observational learning takes place and examined the factors that influence it. Let’s now take a look at five possible outcomes of observational learning as they occur in classrooms: directing attention, encouraging existing behaviors, changing inhibitions, teaching new behaviors and attitudes, and arousing emotions (Schunk, 2012).

DIRECTING ATTENTION. By observing others, we not only learn about actions but also notice the objects involved in the actions. For example, in a preschool class, when one child plays enthusiastically with a toy that has been ignored for days, many other children may want to have the toy, even if they play with it in different ways or simply

Connect and Extend to PRAXIS II®

Observational Learning (II, B2)

Identify situations in which observational learning may be a wise approach, and describe the essential elements of effective observational learning.

Direct reinforcement

Reinforcement given after successful completion of a task.

Vicarious reinforcement

Increasing the chances that we will repeat a behavior by observing another person being reinforced for that behavior.

Self-reinforcement

Controlling (selecting and administering) your own reinforcers.

carry it around. This happens, in part, because the children's attention has been drawn to that particular toy. I can remember trying to teach my middle school students difficult vocabulary words by providing definitions. One day I asked students take turns writing a funny sentence on the board that included the target word. Watching their peers stand in front of the class held the students in rapt attention.

FINE TUNING ALREADY-LEARNED BEHAVIORS. All of us have had the experience of looking for cues from other people when we find ourselves in unfamiliar situations. Observing the behavior of others tells us which of our already learned behaviors to use: the proper fork for eating the salad, when to leave a gathering, what kind of language is appropriate, and so on. Adopting the dress and grooming styles of TV or music idols is another example of this kind of effect.

STRENGTHENING OR WEAKENING INHIBITIONS. If class members witness one student breaking a class rule and getting away with it, they may learn that undesirable consequences do not always follow rule breaking. If the rule breaker is a well-liked, high-status class leader, the effect of the modeling may be even more pronounced. This **ripple effect** (Kounin, 1970) can work for the teacher's benefit. When the teacher deals effectively with a rule breaker, especially a class leader, the idea of breaking this rule may be inhibited for the other students viewing the interaction. This does not mean that teachers must reprimand each student who breaks a rule, but once a teacher has called for a particular action, following through is an important part of capitalizing on the ripple effect.

TEACHING NEW BEHAVIORS. William James (1899/2001) said, "The teacher who meets with the most success is the teacher whose own ways are the most imitable" (p. 26). Modeling has long been used to teach dance, sports, and crafts, as well as skills in subjects such as food science, chemistry, and welding. Cognitive modeling can also be applied deliberately in the classroom to teach mental skills and to broaden horizons—to teach new ways of thinking, such as thinking through the steps in a complex math problem. Teachers serve as models for a vast range of behaviors, from pronouncing vocabulary words to reacting to the seizure of a student with epilepsy, to being enthusiastic about learning. For example, a teacher might model critical thinking skills by thinking "out loud" about a student's question. Or a high school teacher concerned about girls who seem to have stereotyped ideas about careers might invite women with nontraditional jobs to speak to the class or expose the girls to exemplary models in science, technology, engineering and mathematics (STEM), for example (see engineergirl.org). Teachers can share their love of reading or music or art or history by sharing their favorite books, films, artists, and so on. Studies indicate that modeling can be most effective when the teacher makes use of all the elements of observational learning—attention, retention, production, and especially reinforcement and practice. It is important to select appropriate models, however. For example, students who doubt their own abilities might be best paired with a peer who keeps trying and finally masters the material (Schunk, 2016).

AROUSING EMOTION. Finally, through observational learning, people may develop emotional reactions to situations they have never experienced personally. Hearing, watching, or reading about a situation are powerful forms of observation. This may be most obvious through fear-inducing observations. News reports of shark attacks have many of us anxious about swimming in the ocean. The tragedies of school shootings reported on television prompt parents, teachers, and students alike to develop new concerns over safety in schools. Some terrible examples of modeling occur with "copy-cat killings" or suicide clusters in schools. When frightening things happen to people who are similar in age or circumstances to your students, they may need to be given an opportunity to talk about their emotions. But not all observations lead to negative emotions. Watching or reading about the courageous acts of others who spend their lives advocating for human and civil rights can lead to emotional responses that promote

Ripple effect
"Contagious" spreading
of behaviors through
imitation.

GUIDELINES

Using Observational Learning

Model behaviors and attitudes you want your students to learn.

Examples

1. Show enthusiasm for the subject you teach.
2. Be willing to demonstrate both the mental and the physical tasks you expect the students to perform. I once saw a teacher sit down in the sandbox while her 4-year-old students watched her demonstrate the difference between “playing with sand” and “throwing sand.”
3. Model good problem solving—think out loud as you work through a difficult problem. A language arts teacher might stop and say, “Now let me see if I remember what happened so far,” or “That was a hard sentence. I’m going to read it again.”
4. Model coping skills, persistence, and effort. Engage with a difficult problem, even if you seem to reach a dead end. Try new strategies or take a break and return to the problem later.
5. Model your expectations. I remember seeing my fellow teachers talking to one another during a school assembly while occasionally looking up to chastise students who were doing the same thing! Students detest hypocrisy. Promote desired behaviors by engaging in them yourself.

Use peers, especially class leaders, as models.

Examples

1. In group work, pair students who do well with those who are having difficulties.

2. When choosing a model, alternate between *coping models* who work through problems slowly and correct their errors as they work and *mastery models* who solve problems quickly and without error.
3. Ask students to demonstrate the difference between “whispering” and “silence—no talking.”

Make sure students see that positive behaviors lead to reinforcement for others.

Examples

1. Point out the connections between positive behavior and positive consequences in stories.
2. Be fair in giving reinforcement. The same rules for rewards should apply to both the students with problems and the students who do not cause trouble.

Enlist the help of class leaders in modeling behaviors for the entire class.

Examples

1. Ask a well-liked student to be friendly to an isolated, fearful student.
2. Let high-status students lead an activity when you need class cooperation or when students are likely to be reluctant at first. Popular students can model dialogues in foreign-language classes or be the first to tackle dissection procedures in biology.

For more information on observational learning, go to www.readwritethink.org/ and search for “modeling.”

social change. Indeed, diverse media have made it possible to bring unimaginable realities that we would never experience to our fingertips, both at home and at school. This can engender new forms of compassion and understanding. Seeing media portrayals of acts of kindness or heroism can arouse emotion that may prompt imitative behaviors or “faith” in humanity.

The *Guidelines: Using Observational Learning* will give you some ideas about using observational learning in the classroom.

One final thing you can do to promote healthy observational learning is to help your students select appropriate models. Bandura (2016) pointed out that the environments in which we live are not just externally imposed; we have some say in how we select and create our social environments. For example, high school students choose their classes, their peer groups, their extracurricular activities, and even their social media friends. Helping students reflect on how these social groups influence their behaviors might enable them to choose more wisely. Of course, learners must feel some sense of choice and capability in the matter. Indeed, the next central element of social cognitive theory is self-efficacy, a belief that is especially important in learning and teaching.

AGENCY AND SELF-EFFICACY

Remember that social cognitive theory emphasizes the dynamic interaction of personal, behavioral, and environmental events in shaping human lives. Bandura (1997) placed particular emphasis on the personal factors. Because of people's capacity for self-influence, we have a role in determining what we learn, with whom we interact, and how we act. Bandura (2016) called this **human agency**—"To be an agent is to exert intentional influence over one's functioning and over the course of events by one's actions" (p. 4). Agency involves the ability to make intentional choices and plans, design appropriate courses of action, and then motivate and regulate the execution of these plans and actions. This is the major difference between social cognitive theory and behaviorism: In social cognitive theory, we can change our environments, control our own behavior, support the actions of others, and take charge of our lives. Behaviorism removes the "personal" from the equation, and focuses on predicting behaviors entirely by the reinforcing (or punishing) environment. When we discuss self-regulation later in the chapter, you will see how students and teachers can become more *agentic*—more self-directing and in charge of their own learning and motivation.

Central to our own agency are the beliefs we hold about our own capabilities, referred to as **self-efficacy**. Consider how learners imagine various outcomes of their behavior. "Will I succeed or fail? Will I be liked or laughed at?" "Will I be more accepted by teachers in this new school?" How students answer these questions depends on their beliefs about their personal competence or effectiveness in a given area. Bandura (1997) defined self-efficacy as "beliefs in one's capabilities to organize and execute the courses of action required to produce given attainments" (p. 3). Simply put, self-efficacy answers the question, "Can I do this?" We ask ourselves this question about all sorts of situations—Can I do math? Can I keep my cool when my friend talks about me behind my back? Can I teach this group of students? Can I do 10 pushups? Can I stop checking my phone 100 times a day for new messages? Researchers have shown that self-efficacy is essential for positive student outcomes across grade levels and content domains. Students with high self-efficacy exert greater levels of effort, persistence, and resilience when engaged in challenging tasks—as well as experience lower levels of stress and anxiety for the task (Bandura, 1997; Honicke & Broadbent, 2016; Klassen & Usher, 2010). In a study of students going from middle through high school, students with a higher level of self-efficacy for having control over their academic outcomes had higher levels of confidence in their academic abilities, earned higher grades, and were more likely to graduate (Caprara, Pastorelli, Regalia, Scabini, & Bandura, 2005).

Self-Efficacy, Self-Concept, and Self-Esteem

Most people assume self-efficacy is the same as self-concept or self-esteem, but it isn't. Although these terms refer to self-beliefs, they differ in important ways. *Self-efficacy* refers to a "context-specific assessment of competence to perform a specific task" (Pajares, 1997, p. 15). *Self-concept*, on the other hand, has historically referred to a more global self-perception. One's self-concept is judged by both external and internal comparisons, using other people or other aspects of the self as frames of reference (Marsh, Xu, & Martin, 2012). But self-efficacy focuses on your ability to successfully accomplish a particular task with no need for comparisons—the question is whether *you* can do it, not whether others would be successful. Also, self-efficacy beliefs are strong predictors of behavior, but self-concept has typically shown weaker predictive power (Anderman & Anderman, 2014; Bandura, 1997).

Self-efficacy is "context specific," which means it varies, depending on the subject or task. For example, my sense of efficacy for singing is really low, but I feel confident in my ability to read a map and navigate (except in certain cities like Rome that are hopeless). Even young students have different efficacy beliefs for different tasks. One study found that by the first grade, students already differentiated among their sense of efficacy for reading, for writing, and for spelling (Wilson & Trainin, 2007).

Human agency The capacity to coordinate learning skills, motivation, and emotions to reach your goals.

Self-efficacy A person's sense of being able to deal effectively with a particular task. Beliefs about personal competence in a particular situation.

Self-efficacy is concerned with judgments of personal competence; self-esteem is concerned with judgments of self-worth (Usher, 2015). Self-esteem is determined in large part by the value we place on our performance in a domain (math, appearance, singing, soccer, etc.) and our concern over what others think about our competence (Harter & Whitesell, 2003). Self-esteem is not affected if we feel incompetent in areas we don't really value. There is no direct relationship between self-esteem and self-efficacy. It is possible to feel highly efficacious in one area and still not have a high level of self-esteem, or vice versa (Valentine, DuBois, & Cooper, 2004). For example, as I confessed earlier, I have very low self-efficacy for singing, but my self-esteem is not affected, probably because my life does not require singing. But if my self-efficacy for teaching a particular class (my teaching self-efficacy) started dropping after several bad experiences, I know my self-esteem would suffer because I value teaching.

Sources of Self-Efficacy

How is it that we come to believe we are capable in one area and hopeless in another? Bandura (1997) identified four sources of self-efficacy: mastery experiences, vicarious experiences, social persuasion, and physiological and emotional arousal. **Mastery experiences** refer to how we interpret our own direct experiences—usually this is the most powerful source of efficacy information. Successes raise efficacy beliefs, while failures lower them. Bandura (1997) also refers to these as “enactive” experiences, given that we do not necessarily interpret all of our performances as masterful.

Sometimes we have little or no direct experience in a domain. We can therefore base our self-efficacy judgments on other sources, such as the **vicarious experiences** we have through observing the performances of others. Watching a model not only teaches us new ways of doing things but also alters our beliefs about what we can do. When I was young, my close friend could play a fierce Mozart sonata. With my chin perched at the end of the keyboard, I watched her fingers glide across the keys and said to myself, “If she can play this, then I can too.” When an observer feels similar to the model, the vicarious influence on self-efficacy is stronger (Schunk et al., 2014). In school, a peer's good performance can enhance other students' own sense of efficacy. When an esteemed model fails, observers' self-efficacy decreases. There are some exceptions to this pattern, however. For example, watching someone struggle using poor skills might convince an observer that he can succeed at the same task by implementing better skills.

The popularity of skill-based television programs that model how to cook, redesign your kitchen, improve your golf swing, or do yoga demonstrates the influence of vicarious experiences. These are particularly effective when viewers can identify with the subject in the show. In some circumstances, vicarious experiences can be a powerful source of self-efficacy. Keyser and Barling (1981) found that sixth graders relied most on modeling as a source of self-efficacy information. Similarly, models have been shown to play an important role in the self-efficacy of women who have pursued careers in science and engineering (Zeldin, Britner, & Pajares, 2008).

A third source of self-efficacy, **social persuasion**, refers to the evaluative messages students receive from those around them. These messages take many forms, both overt, like a “pep talk” or specific performance feedback, and covert, such as a teacher's tendency to avoid calling on certain students to answer difficult questions. Social persuasion alone may not always create enduring increases in self-efficacy, but a persuasive boost in self-efficacy can lead a student to make an effort, attempt new strategies, or try hard enough to succeed (Bandura, 1982). Social persuasion from peers or trusted experts such as teachers can counter occasional setbacks that might have instilled self-doubt and interrupted persistence. The potency of persuasion depends on the credibility, trustworthiness, expertise, and/or status of the persuader. During skill development, people may be more inclined to pay attention to what others tell them about their abilities (Bandura, 1997). Social persuasion that highlights prior successes (mastery) in similar tasks, identifies short-term goals and accomplishments, or focuses on the importance of effort are more likely to promote success in boosting

Connect and Extend to PRAXIS II®

Modeling (II, B2)

Teachers often use modeling to teach students new behaviors. Identify the characteristics that tend to make models effective in instructional contexts.

MyLab Education Podcast 11.1

Textbook author Anita Woolfolk explains the sources of self-efficacy and how teachers might use this information to invent ways of supporting their students' sense of efficacy for learning. Why is the belief about yourself so important, and where does it come from?

Mastery experiences Our own direct experiences—the most powerful source of efficacy information.

Vicarious experiences Accomplishments that are modeled by someone else.

Social persuasion A “pep talk” or specific performance feedback—one source of self-efficacy.

TABLE 11.2 • Sources of Self-Efficacy

SOURCE	EXAMPLE
Mastery Experiences	Past successes and failures in similar situations, as perceived by the individual. To increase self-efficacy, the success must be attributed to the ability, effort, choices, and strategies of the individual—not to luck or extensive help from others.
Vicarious Experiences	Seeing other people like you succeed on a task or reach a goal that is similar to the one you face.
Social Persuasion	Encouragement, informational feedback, useful guidance from a trusted source, evaluation.
Physiological Arousal	Positive or negative arousal—excitement and a feeling of being “psyched” and ready (increases self-efficacy) or a sense of anxiety and foreboding (decreases self-efficacy).

self-efficacy and initiating successful performance (Bandura, 1997; Schunk et al., 2014; Usher & Pajares, 2008).

A final source of self-efficacy is the level of **physiological or emotional arousal** that you experience before or during an activity. For instance, the thought of giving a public speech makes a high school student's palms sweat and his chest tighten. He interprets this as a sign that he is not capable of speaking. We read our emotions and bodies in ways that alter our perceptions of our capabilities (Bandura, 1997; Schunk et al., 2014; Usher & Pajares, 2009). As you think about the task of teaching, are you anxious and worried (lowers self-efficacy) or excited and “psyched” (raises self-efficacy)? At times you can help students reappraise or relabel their arousal—they are not anxious, they are psyched and ready!

Table 11.2 summarizes the sources of self-efficacy. Some evidence suggests that students from different group memberships interpret the source of self-efficacy in distinct ways (Usher & Pajares, 2008). For example, Butz and Usher (2015) asked 2,500 upper elementary and middle school students about the sources of their self-efficacy in reading and math. Girls were more likely to list social sources of their self-efficacy (i.e., vicarious experience and social persuasion) than were boys. The researchers also found that students reported different sources of self-efficacy in the two academic disciplines, which suggests that what makes a student confident in one subject area might not work in another. Other cultural differences can affect on how self-efficacy develops. One study found that the math self-efficacy of adolescents in Korea and the Philippines was based more on social persuasion from peers and parents; for U.S. adolescents, vicarious experience from teachers and friends was also an important source of self-efficacy (Ahn, Usher, Butz, & Bong, 2016). All four of the sources in Table 11.2 were identified as supporting self-efficacy development for third-grade students in France (Joët, Usher, & Bressoux, 2011).

Self-Efficacy in Learning and Teaching

STOP & THINK On a scale from 1 to 100, how confident are you that you will finish reading this chapter today? •

Let's assume your sense of efficacy is around 90 for completing this chapter. Higher self-efficacy leads to greater effort and persistence in the face of setbacks, so even if you are interrupted in your reading, you are likely to return to the task. I believe I can finish writing this section today, so I have resumed work on it after my computer crashed and

MyLab Education Video Example 11.3

The high school teacher in this video challenges students, but also provides supports. She gives her English learners opportunities to work collaboratively and learn from peer models. Observe the ways her teaching might help students develop a sense of self-efficacy about math skills.

Physiological or emotional arousal Physical and psychological reactions causing a person to feel alert, attentive, wide awake, excited, or tense.

GUIDELINES

Encouraging Self-Efficacy

Emphasize students' progress in a particular area.

Examples

1. Return to earlier material in reviews, and show how "easy" it is now.
2. Encourage students to improve projects when they have learned more.
3. Keep examples of particularly good work in portfolios as well as work that shows growth and improvement over time, and periodically have students review and reflect on their improvements.

Set learning goals for your students, and model a mastery orientation for them.

Examples

1. Guide students to set goals that focus on gaining skill, competency, or understanding.
2. Recognize progress and improvement. Avoid nonspecific praise.
3. Share examples of how you have developed your abilities in a given area, and provide other models of achievement who are similar to your students—no supermen or superwomen whose accomplishments seem unattainable.
4. Read stories about diverse students who overcame physical, mental, or economic challenges.

5. Don't excuse failure because a student has problems outside school. Help the student succeed inside school.

Make specific suggestions for improvement, and revise grades when improvements are made.

Examples

1. Return work with specific comments noting what the students did right, what they did wrong, and why they might have made the mistakes.
2. Experiment with peer editing.
3. Show students how their revised, higher grade reflects greater competence and raises their class average.

Stress connections between past efforts and past accomplishments.

Examples

1. Have individual goal-setting and goal-review conferences with students, in which you ask students to reflect on how they solved difficult problems.
2. Confront self-defeating, failure-avoiding strategies directly.

For more information on self-efficacy, go to the "P20 Motivation and Learning Lab" at the University of Kentucky.

I had to start over on several pages. Of course, that could make for a late night, because I am going to a San Francisco Giants baseball game at 7:00 tonight and may have to finish the section after the game.

Self-efficacy also influences motivation and performance through goal setting. If we have a high sense of efficacy in a given area, we will set higher goals, be less afraid of failure, and find new strategies when old ones fail. If your sense of efficacy for reading this chapter is high, you are likely to set high goals for completing it—maybe you will take some notes, too. If your sense of efficacy is low, however, you may avoid the reading altogether or give up easily when problems arise or you are interrupted with a better offer (Bandura, 1993, 1997; Schunk & Usher, 2012).

Research indicates that performance in school is improved and self-efficacy is increased when students (a) adopt short-term goals so it is easier to judge progress; (b) are taught to use specific learning strategies such as outlining or summarizing that help them focus attention; and (c) receive rewards based on achievement, not just engagement, because achievement rewards signal increasing competence (Pajares, 2006). See the *Guidelines: Encouraging Self-Efficacy* for ideas about how you can support students' self-efficacy (and your own!).

What is the most motivating level of efficacy? Should students be accurate, optimistic, or pessimistic in their estimations? Evidence indicates that a higher sense of self-efficacy supports motivation, even when the belief is a slight overestimation. Children and adults who are optimistic about the future are more mentally and physically healthy, less depressed, and more motivated to achieve (Flammer, 1995; Seligman, 2006). After examining almost 140 studies of motivation, Sandra Graham concluded that these qualities

MyLab Education Podcast 11.2

There are three kinds of efficacy judgments at work in schools: student, teacher, and collective. All three kinds are related to student achievement, even after considering the powerful effects of SES. Textbook author Anita Woolfolk describes them and gives ideas for increasing each kind of efficacy.

characterize many African American students. She found that the African American students studied had strong self-concepts, resilience, and high expectations, even in the face of difficulties (Graham, 1996; Graham & Taylor, 2002). Students who show academic resilience are more likely to succeed because they can effectively manage the stressors and barriers in their academic life (Martin & Marsh, 2009).

As you might expect, there are dangers in underestimating one's capabilities because then students are more likely to put forth a weaker effort and give up more easily. But there are dangers in continually overestimating one's efficacy as well. Students who think that they are better readers than they actually are may not be motivated to go back and repair misunderstandings as they read. They don't discover that they didn't really understand the material until it is too late (Pintrich & Zusho, 2002; Usher & Schunk, 2017).

In schools, we are particularly interested in self-efficacy for learning mathematics, writing, history, science, sports, and other subjects, as well as self-efficacy for using learning strategies and for handling the many other challenges classrooms present. Consider a few findings from research with students. Self-efficacy is related to school performance for students from third grade through college (Fast et al., 2010; Honicke & Broadbent, 2016; Kenney-Benson, Pomerantz, Ryan, & Patrick, 2006), life satisfaction for adolescents (Vecchio, Gerbino, Pastorelli, Del Bove, & Caprara, 2007), use of deep processing learning strategies for college students (Prat-Sala & Redford, 2010), choice of college major (Pajares, 2002), and performance in college for older students (Elias & MacDonald, 2007). The value of self-efficacy seems to cut across cultural contexts. For example, self-efficacy is related to math/science goals and interests for Mexican American youth (Navarro, Flores, & Worthington, 2007), staying in school for Italian secondary students (Caprara et al., 2008), language performance for French elementary school students (Joët et al., 2011), academic achievement in math for both male and female middle school students (Kenney-Benson et al., 2006), and mathematics achievement for both Anglo and South Asian Canadian middle school students (Klassen, 2004).

Maybe you are thinking, sure, higher self-efficacy is related to higher achievement because students who have more ability have higher self-efficacy. But these relationships between self-efficacy and achievement hold even when we take ability into account. For example, when students with the same ability in math are compared, the ones with higher self-efficacy for math perform better in math (Wigfield & Wentzel, 2007). Self-efficacy encourages higher goals, persistence, and effort. People with high self-efficacy are better equipped to take charge of their own lives—they can act with *agency*.

Teachers' Sense of Efficacy

You saw in Chapter 1 that much of my own research has focused on **teachers' sense of efficacy**, defined as a teacher's belief that he or she can reach even difficult students to help them learn. This confidence belief appears to be one of the few personal characteristics of teachers that predict student achievement (Klassen, Tze, Betts, & Gordon, 2011; Tschannen-Moran, Woolfolk Hoy, & Hoy, 1998; Woolfolk Hoy, Hoy, & Davis, 2009; Zee & Koomen, 2016). When teachers take responsibility for student success or failure (rather than assigning that responsibility to student ability or to external barriers), then the teachers are more "intentional" in their approaches to reaching their students and are more successful in meeting their learning needs (Putman, Smith, & Cassady, 2009). A review of 165 studies showed that teachers with higher self-efficacy report greater job satisfaction and commitment and lower feelings of burnout (Zee & Koomen, 2016; and see Klassen, Tze, Betts, & Gordon, 2011). Of course, the relationship between teacher self-efficacy and these variables is likely reciprocal—they affect each other. For example, when teachers have a higher sense of efficacy, they teach more effectively and their students learn more, and when students learn more, teacher self-efficacy grows (Holzberger, Philipp, & Kunter, 2013).

As with any kind of self-efficacy, there may be both benefits and dangers in overestimating one's capabilities. Optimistic teachers probably set higher goals, work harder, reteach when necessary, and persist in the face of problems. But when beginning teachers overrate their abilities, they don't take the steps necessary to improve their

Teachers' sense of efficacy

A teacher's belief that he or she can reach even the most difficult students and help them learn.

skills—until they are confronted with serious problems. So some benefits might follow from having doubts about your efficacy. As Wheatley (2002) pointed out, sometimes, “doubt motivates change” (p. 18).

How does a sense of one’s teaching capabilities develop? Teachers generally rely on the same four sources described earlier when judging their capabilities, although the interplay of these sources may be more complex for teachers than for students (Morris, Usher, & Chen, 2016). Building a flexible set of instructional tools and strong content knowledge helps teachers gain a sense of mastery for their craft. Social sources might be just as powerful as mastery experience when it comes to self-efficacy for teaching. After all, to find out whether we are effective as teachers, we must assess our students’ learning; teaching is an inherently social act. Evaluations by students, parents, and administrators convey important efficacy-related information.

Vicarious experience is another fundamental source of teaching self-efficacy. For example, preservice teachers might watch video playbacks of their own mock lessons or pay close attention to how their cooperating teacher manages the class. Both self-modeling and social modeling can lead to changes in teaching self-efficacy. Klassen and Durksen (2014) found that self-efficacy generally increased and stress decreased during an eight-week practicum for Canadian preservice teachers; however, this trajectory depended on the level of support the preservice teachers received from their cooperating mentor teachers. Working with a proficient model who is also supportive can boost a new teacher’s self-efficacy. Last, teachers also read their own emotional and physiological states related to teaching as a sign of their efficacy or inefficacy for the task. Feeling relaxed and energized when working with youth can convince an aspiring teacher that he or she is capable of pursuing the career. Anxious daydreaming about classroom catastrophes can undermine self-efficacy.

Let’s revisit Bandura’s (1997) powerful assertion that “people’s level of motivation, affective states, and actions are *based more on what they believe* than on what is objectively true” (p. 2, emphasis added). Both teachers’ and students’ beliefs are guides to what they will do and feel. One area in which self-efficacy plays an important role is in self-regulation. Unless we believe we can regulate the many demands of being human, we will likely spend our time reacting to life’s circumstances rather than proactively exercising our own agency. We turn to this issue next. How you can help your students (and yourself) to lead a self-directed, self-regulated life?

MyLab Education **Self-Check 11.3**

SELF-REGULATED LEARNING: SKILL AND WILL

As you may remember from the beginning of this chapter, Albert Bandura said his early education in a tiny school in Canada had given him self-regulation skills that lasted a lifetime. He believes that a major goal of all education is to “equip students with the intellectual tools, self-beliefs, and self-regulatory capabilities to educate themselves throughout their lifetime” (Bandura, 2007, p. 10). **Self-regulation** is the process we use to activate and sustain our thoughts, behaviors, and emotions in order to reach our goals (Perry & Rahim, 2011). When the goals involve learning, we talk about **self-regulated learning**. Self-regulated learners have the *skill* and *will* to learn—they are “metacognitive, motivated to learn, and strategic” (Perry & Rahim, 2011, p. 122). This means they have a combination of academic learning skills, self-awareness, self-control, and motivation for learning. Definitions of self-regulation have varied according to which of those features are emphasized (Burman, Green, & Shanker, 2015).

To continue learning independently throughout life, you must be self-regulated—what we refer to in conversations as a *self-starter*. Self-regulation may be even more important today as knowledge about virtually anything is available instantly on the Internet. How do you persist and stay focused on your goal as you browse all that information

Self-regulation Process of activating and sustaining thoughts, behaviors, and emotions in order to reach goals.

Self-regulated learning

A view of learning as skills and will applied to analyzing learning tasks, setting goals and planning how to do the task, applying skills, and especially making adjustments about how learning is carried out.

and are distracted by texts, tweets, and fascinating pictures of cute kittens . . .? Or, as one blog post asked, “Do you control your technological devices or do they control you?”

STOP & THINK Think about the class you are taking where you are using this textbook. On a 7-point scale—from 1 = *not at all true of me*, to 7 = *very true of me*—answer the following questions:

1. When I study for a test, I try to put together the information from class and from the book.
2. When I do homework, I try to remember what the teacher said in class so I can answer the questions correctly.
3. I know I will be able to learn the material for this class.
4. I ask myself questions to make sure I know the material I have been studying.
5. Even when study materials are dull and uninteresting, I keep working until I finish. •

By answering the questions in the *Stop & Think*, you have just responded to five items from the Motivated Strategies for Learning Questionnaire (MSLQ) (Midgley et al., 1998; Pintrich & De Groot, 1990). This questionnaire has been used in hundreds of studies to assess students’ self-regulated learning and motivation. How did you do? The first two questions assess your use of *cognitive strategies*, like those we discussed in Chapter 9. The third question assesses your *sense of efficacy* for this class. But the last two questions (4 and 5) specifically assess *self-regulation*.

Self-regulated learners transform their mental abilities, whatever they are, into academic skills and strategies. Many studies link self-regulated strategy use to measures of academic achievement, especially for middle school and high school students. For younger students, self-regulation of attention and emotion are particularly important for learning and achieving in school (Dent & Koenka, 2016; Valiente, Lemery-Chalfant, & Swanson, 2010). In fact, one study found that when students in a first-grade class had better self-regulated learning skills, individual students in that class improved in vocabulary learning and reading comprehension. So, being in a class with peers who had good self-regulation skills supported literacy development in individual students (Skibbe, Phillips, Day, Brophy-Herb, & Connor, 2012).

What Influences Self-Regulation?

The concept of self-regulated learning integrates much of what is known about effective learning and motivation. As you can see from the processes just described, three factors influence skill and will: knowledge, motivation, and self-discipline or volition. In addition, there are developmental differences among students.

KNOWLEDGE. To be self-regulated learners, students need knowledge about themselves, the subject, the task, strategies for learning, and the contexts in which they will apply their learning. “Expert” students know about themselves and can reflect on their own learning processes. This “metacognitive knowledge” (remember that *metacognition* refers to thinking about your own thinking) includes knowing your preferred learning approaches, what is easy and what is hard about learning certain material, coping strategies for handling difficult material, your interests and talents, and how to use your strengths (Efklides, 2011). Experts also know quite a bit about the subject being studied, and they can adapt their knowledge to meet new demands; the more they know, the easier it is to learn more (Alexander, Schallert, & Reynolds, 2009). They are more likely to understand that different learning tasks require different approaches on their part. A simple memory task, for example, might require a mnemonic strategy (see Chapter 8), whereas a complex comprehension task might be approached by means of concept maps of the key ideas (see Chapter 9). Also, these self-regulated learners know that learning is often difficult and knowledge is seldom absolute; there usually are different ways of looking at problems as well as different solutions (Greene, Muis, & Pieschl, 2010; Winne, 2017).

MyLab Education
Video Example 11.4

The teen in this video answers questions about school—what he likes and dislikes. As you listen, think about comments that indicate his level of self-regulation. Do you think he is a self-regulated learner?

These expert students not only know what each task requires but also can apply the strategy needed. They can skim or read carefully. They can use memory strategies or reorganize the material. As they become more knowledgeable in a field, they apply many of these strategies automatically. In short, they have mastered a large, flexible repertoire of learning, help-seeking, and coping strategies (see Chapter 9). Finally, self-regulated learners think about the contexts in which they will apply their knowledge—when and where they will use their learning—so they can set motivating goals and connect their present efforts to their accomplishments (Winne, 2017). Clearly, both content knowledge and self-knowledge play an important role in whether students will be self-regulated. Teachers must therefore help students develop both content knowledge and a greater awareness of their own cognitive and learning processes. Later in the chapter, we consider some suggestions for how to do this.

MOTIVATION. Knowing about what is needed to accomplish your learning goals is important, but it may not be sufficient. Motivation also influences the degree to which students regulate their own learning. In Chapter 12 you will learn about many facets of motivation, but let's consider a few that researchers have found to be related to self-regulated learning. Students who demonstrate greater individual interest in an activity tend to be better at regulating themselves in that activity (Renninger & Hidi, 2016; Thoman, Sansone, & Geerling, in press). My neighbor, a 10-year-old basketball enthusiast, can spend hours shooting hoops in her driveway, drawing elaborate defense plans for her team, and studying the moves of her role models. Activities that are valued, whether for their utility in getting us to the next level or simply for the enjoyment they bring, can lead us to deeper and more systematic engagement (Eccles, Fredricks, & Baay, 2015). Motivational beliefs also influence self-regulation. For example, students who have higher self-efficacy for managing their learning tasks (i.e., self-efficacy for self-regulation) not only use more effective self-regulatory strategies but also perform better in school (Usher & Schunk, 2017). In addition they believe their own intelligence and abilities are improvable (Job, Walton, Bernecker, & Dweck, 2015). Even if they are not intrinsically motivated by a particular task, they are serious about getting the intended benefit from it. Those who believe in their capabilities can better focus their attention and other cognitive and emotional resources for the task at hand. They know why they are studying, so their actions and choices feel more self-determined and less controlled by others (Zimmerman, 2011). But knowledge and motivation are not always enough. Self-regulated learners need volition or self-discipline. Lyn Corno once said, "Where motivation denotes commitment, volition denotes follow-through" (Corno, 1992, p. 72).

VOLITION. I am one month behind in this project. I have been up writing at 5:00 a.m. every day since I got back from Taiwan (great place!) where I gave a series of talks. I am still jet lagged, barely awake, but I want to keep writing because the deadline for this chapter is very near (well, passed actually). I have knowledge and motivation, but to keep going I need a good dose of volition. Volition is an old-fashioned word for will-power. The more technical definition for volition is *protecting opportunities to reach goals*. Typically, students need volition to overcome the resistance they feel when they experience a conflict between two desired outcomes (Oettingen, Schrage, & Gollwitzer, 2015). For example, you might need an act of volition to decide between hanging out with friends or reading a book that is needed for a report due in a few weeks. In this way, an act of volition is *voluntary*, that is, a *free will* behavior.

Volition is influenced by the individual's level of perceived control for the given task (Efklides, 2011). People are more likely to exercise volitional control when they have experience in sticking with tasks to reach their goals, becoming active agents in achieving success (Metcalf & Greene, 2007). I can stick with this writing because I have done it before and held the finished book. Self-regulated learners know how to protect themselves from distractions—where to study, for example, so they are not interrupted. They choose methods to cope, even when they feel anxious, drowsy, or lazy (Corno, 2011; Snow, Corno, & Jackson, 1996). And they know what to do when they are tempted to stop working and

Volition Will power; self-discipline; work styles that protect opportunities to reach goals by applying self-regulated learning.

POINT/COUNTERPOINT: Are “Grittier” Students More Successful?

Most of us would agree that those who passionately persist toward their goals tend to meet with more success. Grit might be one important aspect of the volition component of self-regulation, but does it warrant all the attention it is receiving? Some education researchers have cast doubt on grit as a new construct, citing mixed evidence of its relationship to success. These scholars emphasize that other self-regulatory factors are just as (if not more) important for determining student success. Let’s look at these perspectives more closely.

POINT ▶ **Grit is essential for student success, and teachers should therefore promote it.** The jacket of Paul Tough’s 2012 bestselling book, *How Children Succeed*, begins with the age-old question, “Why do some children succeed while others fail?” His answer is in his subtitle: *Grit, Curiosity, and the Hidden Power of Character*. Tough argues that success in school requires more than outstanding intellectual abilities and talent. To end up at the top of one’s class requires not just talent but a repertoire of “soft” skills—sometimes called “noncognitive factors” (Farrington et al., 2012). For Tough, such skills may be the deciding factor in whether children can escape dire circumstances: “There is no antipoverty tool we can provide for disadvantaged young people that will be more valuable than the character strengths . . . [such as] conscientiousness, grit, resilience, perseverance, and optimism” (p. 189). Tough’s claims lean on the work of psychologist and former school teacher Angela Duckworth, who similarly wondered whether factors other than IQ or talent—things like effort, determination, self-control, persistence, and what she named *grit*—might actually be just as important in predicting success.

To investigate this, Duckworth and her associates asked hundreds of young people to rate their grittiness by responding to items like “I finish whatever I begin,” and “I am diligent” (see www.angelaeduckworth.com). They found that

students with higher grit scores also had higher SAT scores and grades (Duckworth et al., 2007; Duckworth & Quinn, 2009). Grittier kids placed higher in the National Spelling Bee competition (Duckworth & Quinn, 2009). Chicago high school juniors with more grit were more likely to graduate on time (Eskreis-Winkler, Duckworth, Shulman, & Beal, 2014). These findings often held true even when ability measures (IQ, past GPA) were included as predictors. Teachers’ level of grit was found to predict novice teachers’ effectiveness (Duckworth, Quinn, & Seligman, 2009).

How can grit predict success better than one’s previous success? Duckworth (2016) offers her theory: “When you consider individuals in identical circumstances, what each achieves depends on just two things, talent and effort . . . but effort factors into the calculations twice, not once” (p. 42). In their respective 2016 books, Duckworth and Tough argue that even though grit is a personality trait, it can also be cultivated. Their books highlight stories from numerous paragons of grit and offer tips for how parents, teachers, and leaders can promote gritty individuals. Although both authors have cautioned readers that promoting students’ grit may not be an easy fix, their books are flying off the shelves. The two are frequently invited keynote speakers at meetings for school leaders across the United States. Clearly, grit has found a solid fan base among educators. But grit also has its fair share of critics.

have (another) cup of coffee—the temptation I’m facing now—that, and a beautiful Florida day that beckons me to sweep out the garage (sweeping my garage always looks appealing when I face a tough writing job—cleaning closets is a close second).

Volition is deliberate and effortful, but with practice it can become more automatic—a habit or a “work ethic” (Corno, 2011). William James knew this over 100 years ago. One of my favorite James quotes is about making volition a habit. He said: “Do every day or two something for no other reason than that you would rather not do it, so that when the hour of dire need draws nigh, it may find you not unnerved and untrained to stand the test” (James, 1890, IV, p. 126).

You may have heard of two concepts related to volition: self-control and grit. Both concepts have received growing attention in recent years. *Self-control* has been defined as “the capacity to regulate attention, emotion, and behavior in the presence of temptation” (Duckworth & Gross, 2014, p. 319). Walter Mischel’s famous delay of gratification experiment offers a glimpse into the importance of self-control (Mischel, 2014). He offered 4-year-old children an enticing marshmallow to eat, and promised to give a second marshmallow to those who could postpone eating the first marshmallow until he returned from a 15-minute errand (that’s a long time!). Most children gobbled up the first marshmallow before he returned; but others waited, employing various self-control strategies to help them resist the temptation. (You can view this experiment online in several funny YouTube videos.) Mischel and his colleagues then conducted follow-up studies with these children over a period of many years. They were shocked at what they found. Children who had exercised self-control by waiting for the second marshmallow had higher SAT scores, responded

A focus on grit as the key to success is too narrow.

Education policy makers and researchers have been wary about the phenomenon of grit as a key to success. Grit's popularity has spawned contentious commentary in media outlets such as *The Atlantic* ("The Limitations of Teaching 'Grit' in the Classroom," "Is Grit Overrated? The Downsides of Dogged, Single-Minded Persistence"), *The New York Times* ("Putting Grit in Its Place"), and *EdWeek* ("Is 'Grit' Racist?"). The debate has several prongs (for a summary, see Alfie Kohn's 2014 article in the *Washington Post*, "Ten Concerns About the 'Let's Teach Them Grit' Fad"). First, some argue that to focus on grit, an individual-level variable, as the deciding factor in student success is to blame students for their own school (mis)fortunes and to let schools off the hook; this distracts from examining systemic inequalities that place a greater burden on some students than others (Gorski, 2016). Furman University Professor Paul Thomas (2014) is among those who see the promotion of grit as veiled racism/classism:

Part of the "grit" narrative includes the assumption that successful students and people (read "White") are successful *primarily* because they work hard; they earn their success. The flip side of this "grit" narrative is that unsuccessful students and people (read "African American" and "Latino/a") are unsuccessful because they simply do not try hard enough.

Second, many have noted that grit appears to be a rebranding of well-researched variables such as conscientiousness, willpower, persistence, and resilience (Rimfeld, Kovas, Dale, & Plomin, 2016). Although Duckworth and her associates have tried to draw distinctions among some of these ideas, such as between grit and self-control (Duckworth & Gross,

2014), researchers have found considerable psychometric overlap between students' responses to grit items and to other measures of self-regulation (Muenks, Wigfield, Yang, & O'Neal, 2017). They question grit's uniqueness.

Third, about that relationship between grit and success? Some recent publications show that the relationship is not as conclusive as Duckworth and colleagues' earlier work suggested. Researchers Credé, Tynan, and Harms (2017) recently completed a meta-analysis using reports from 66,807 students. They found that in some academic settings, grit is unrelated to students' academic achievement. Results from a recent investigation of Boston-area eighth graders also revealed that grit was not significantly correlated with students' achievement in math or language arts (West et al., 2016). Furthermore, when researchers have considered grit alongside other variables hypothesized to predict student performance, grit loses its predictive power (Meuncks et al., 2016). For example, Usher, Li, Rojas, and Butz (2016) found that self-efficacy (perceived capability in a particular subject area), but not grit (a personality trait), predicted middle school students' grades, standardized test scores, and teachers' ratings in math and reading. Perhaps students are unlikely to persist at something unless they believe they can be successful.

Beware of Either/Or. The idea that success is within reach to anyone willing to show dedication and persistence strikes a powerful chord. Maybe most of us believe as William James (1907) did that "we are making use of only a small part of our possible mental and physical resources." We are intrigued by the hopeful idea that empowering (or debilitating) *psychological factors* can explain the different life outcomes of two people with similar ability. A quick look at Oscar-nominated films reveals our fascination—we pay money to hear and watch stories of dogged perseverance in the face of great odds. They inspire us to consider our own higher potential.

better to stress, had fewer health problems, possessed better social skills, and enjoyed a host of other benefits. Does this mean that some people are just naturally good at self-control and others are not? No, not exactly. Although some children are predisposed for greater self-control, all can learn new self-control strategies (Duckworth, Gendler, & Gross, 2014).

Volition is not always a momentary affair. Sometimes it takes years to accomplish a long-term goal (college degree, anyone?). What does it take to stay committed for the long haul? Researchers have recently claimed that it takes true **grit**—a personality trait characterized by "perseverance and passion to pursue long-term goals" (Duckworth, Peterson, Matthews, & Kelly, 2007, p. 1087). Angela Duckworth and her colleagues claim that students with more grit do better in school and in life (Duckworth, 2016; Duckworth et al., 2007). Over the past decade, grit has become quite a buzzword in education circles. Recent conferences and publications targeting K–12 and higher education personnel have paid a great deal of attention to the subject. Is grit really an important determinant of student success? The *Point/Counterpoint* looks at the evidence from diverse psychological perspectives.

Ultimately, however, the research evidence does not support such a simple story. Social cognitive theory acknowledges that many factors, both internal and external to the individual, must be considered. Yes, self-regulation matters in how successful a learner will be. And a certain level of grit may be one important aspect of self-regulation. But a one-variable approach is insufficient—appealing as it might be. Focusing too much on grit might lead educators to overlook other problems that affect students' self-regulation. As this chapter explains, how self-regulated a learner is requires the engagement of cognitive, metacognitive, motivational, and volitional mechanisms, none of which casts

Grit A a personality trait characterized by determination and persistence.

the deciding vote on whether a student will ultimately succeed. Of course, we must also consider the larger context in which learning takes place. Is what we are asking students to do worth their perseverance and effort in the first place? Does grit come at the expense of other aspects of a quality and “successful” education—such as one’s physical and psychological health, compassion for others, autonomy, and lifelong curiosity? Once again, it’s not as simple as either/or.

DEVELOPMENT OF SELF-REGULATION. How do students develop knowledge, motivation, and volition? The social cognitive theory perspective emphasizes the interaction of personal factors (e.g., neurobiological development, personal beliefs, cognition), environmental/social factors (e.g., support from family, peers, teachers), and behavioral factors. Dale Schunk (1999) proposed a general model of self-regulation development. During childhood, many self-regulation skills must be learned through observation and emulation of others (Schunk & Zimmerman, 1997). Control is gradually transferred from the exemplary models (e.g., teachers) to the individual learner. As learners develop success in applying the skills, they begin to internalize modeled strategies and demonstrate greater levels of self-control. They can eventually engage in independent, adaptive self-regulation in novel situations (also implementing self-reinforcement strategies and enhancing their efficacy for self-regulation).

Self-regulation relies on cognitive functioning too, as explained in Chapters 8 and 9. Three key executive functions that underlie successful self-regulation are inhibitory control (resisting impulsive urges), working memory (holding information in mind while performing other mental operations), and cognitive flexibility (seeing something from different perspectives). These executive functions are necessary for the self-regulation required to solve complex problems (Diamond, 2012). How can teachers and parents promote better executive functioning among learners of all ages? Adele Diamond and Daphne Ling (2016) reviewed results from 84 research studies that tested various interventions. They found that executive functions are impaired under conditions of stress, poor health, or emotional turmoil. They are enhanced when learners are relaxed, healthy (e.g., physically active), and feel a greater sense of connectedness to others. Executive functions are also sharpened when activities are challenging and when frequent opportunities for sustained practice are provided (Diamond, 2012). Teachers and parents can therefore implement various strategies to foster learners’ development of executive functions.

Two social processes support the development of self-regulation: co-regulation and shared regulation. **Co-regulation** is a transitional phase during which students gradually appropriate and internalize self-regulated learning skills through modeling, direct teaching, feedback, and coaching from teachers, parents, or peers. **Shared regulation** occurs when students and teachers work together to regulate each other through reminders, prompts, and other guidance (Hadwin, Järvelä, & Miller, 2017). In Chapter 14 you will read about Lyn Corno’s model of adaptive teaching that intentionally builds student self-regulation development into teaching plans.

There are developmental differences in self-regulation. Self-regulation generally improves over time as learners’ neurobiological systems grow and adapt, but environmental stressors and social isolation can thwart development (Blair & Raver, 2015). Even so, early school experiences can help students get back on track. Gender differences in self-regulation have also been observed. In the early grades, girls may be better at regulating their work than boys (Greene, Muis, & Pieschl, 2010; Matthews, Ponitz, & Morrison, 2009; Mischel, 2014).

What does self-regulation in action look like? How do knowledge, motivation, and volition work together? Let’s examine a self-regulation model from the perspective of social cognitive theory.

A Social Cognitive Model of Self-Regulated Learning

Albert Bandura may have gone from high school graduate to professor at Stanford in 6 years using his self-regulated learning knowledge and skills, but not all of your students will have the ability to be Banduras with established *habits of cognition, motivation,*

Co-regulation A transitional phase during which students gradually appropriate self-regulated learning and skills through modeling, direct teaching, feedback, and coaching from teachers, parents, or peers.

Shared regulation Students and teachers working together to regulate each other through reminders, prompts, and other guidance.

and volition. In fact, many will be like Tracy, a high school student described here by self-regulation expert, Barry Zimmerman:

An important mid-term math exam is two weeks away, and [Tracy] had begun to study while listening to popular music “to relax her.” Tracy has not set any study goals for herself—instead she simply tells herself to do as well as she can on the test. She uses no specific learning strategies for condensing and memorizing important material and does not plan out her study time, so she ends up cramming for a few hours before the test. She has only vague self-evaluative standards and cannot gauge her academic preparation accurately. Tracy attributes her learning difficulties to an inherent lack of mathematical ability and is very defensive about her poor study methods. However, she does not ask for help from others because she is afraid of “looking stupid,” or seek out supplementary materials from the library because she “already has too much to learn.” She finds studying to be anxiety-provoking, has little self-confidence in achieving success, and sees little intrinsic value in acquiring mathematical skill. (Zimmerman, 2002, p. 64)

Clearly, Tracy is unlikely to do well on the test. What would help? For an answer, let’s consider Zimmerman’s (2011) model of self-regulated learning shown in Figure 11.2. According to Zimmerman, self-regulation involves a three-phase cycle—*forethought*, *performance*, and *reflection*. In Phase 1, the *forethought phase*, Tracy needs to set clear, reasonable goals and plan a few strategies for accomplishing those goals. And Tracy’s motivational beliefs make a difference at this point, too. If Tracy had a high self-efficacy for applying the strategies that she planned, if she believed that using those strategies would lead to math learning and success on the test, if she saw some connections between her own interests and the math learning, and if she were trying to master the material—not just look good or avoid looking bad—then she would be on the road to self-regulated learning (Usher & Schunk, 2017).

After thinking about the task at hand, Tracy moves into Phase 2—the *performance phase*. Performing brings new challenges. Now Tracy must have a repertoire of self-control (volitional) and learning strategies. She might use imagery, mnemonics, attention focusing, and other techniques such as those described in Chapters 8 and 9 to remain engaged (Duckworth et al., 2014; Kiewra, 2002). She also will need

to self-observe—monitor how things are going—so she can change strategies if needed. Actual recording of time spent, problems solved, or pages written may provide clues about when or how to make the best use of study time. Turning off the music might help, too.

Finally, Tracy needs to move to Phase 3—the *reflection phase*—by looking back on her performance and reflecting on what happened. Here, her self-regulation involves an evaluation of her performance. What worked and what didn't? Why? If she attributes successes to effort and good strategy use and avoids self-defeating actions and beliefs, she might increase her self-efficacy for doing a similar task in the future. She might also revise her goals for next time or give herself a reward for a job well done. If, on the other hand, Tracy reflects on her own weak efforts, she might pretend not to care or assume she is “no good at math.”

Each phase in Zimmerman's model flows into the next, and the cycle continues as students encounter new learning challenges. You might recall that the capacity for *self-influence* is a hallmark of social cognitive theory (Bandura, 2016). At all phases of the self-regulatory cycle, learners must observe and evaluate themselves. Most of the time, learners' self-regulation depends on their own self-set or internalized standards. On the other hand, “If adequate self-standards are lacking, people exercise little self-directedness” (Bandura, 1986, p. 363). Part of your role as a teacher is helping learners internalize reasonable standards that will help them become good self-regulators.

We have looked at just one theoretical model of self-regulated learning. There are actually several models of self-regulated learning, but all agree that the cognitive processes needed for self-regulated learning require effort (Greene, Muis, & Pieschl, 2010; Puustinen & Pulkkinen, 2001; Usher & Schunk, 2017; Winne, 2011, 2017). Let's now look at two classroom examples.

Reaching Every Student: Examples of Self-Regulation in Two Classrooms

Students differ in their self-regulation knowledge and skills. But teachers must work with an entire classroom, and still “reach every student.” Here are two examples of real situations where teachers did just that. The first involves writing, the second math problem solving—both complex tasks.

WRITING. Carol is a second-grade student described by Nancy Perry and Lynn Drummond (2002). Ms. Lynn was Carol's teacher; she characterizes Carol as “a very weak writer.” Carol has difficulty finding facts and then transforming those facts into meaningful prose for a research report. Also, she has difficulty with the mechanics of writing, which, according to Ms. Lynn, “holds her back.”

Over the course of the year, Ms. Lynn involved her grade 2 and 3 students in three projects about animals. Through this writing, she wanted students to learn how to (a) do research, (b) write expository text, (c) edit and revise their writing, and (d) use the computer as a tool for researching and writing. For the first report, the class worked on one topic together (Chipmunks). They did the fact-finding and writing together, because Ms. Lynn needed to show them how to do research and write a report. Also, the class developed frameworks for working collaboratively as a community of learners. When they wrote the second report (on Penguins), Ms. Lynn offered students many more choices and encouraged them to depend more on themselves and one another. Finally, for the third report, students chose an animal, conducted a self-regulated research project, and wrote a report. Now that they knew how to do research and write a report, they could work alone or together and succeed at this complex task.

Carol worked with a third-grade boy who was doing research on a related topic. He showed Carol how to use a table of contents and offered advice about how to phrase ideas in her report. Also, Carol underlined words she thought were misspelled so she could check them later when she met with Ms. Lynn to edit her report. Unlike many low-achieving students who have not learned strategies for self-regulating learning, Carol was not afraid to attempt challenging tasks, and she was confident about her

ability to develop as a writer. Reflecting on her progress across the school year, Carol said, “I learned a lot from when I was in grade 1 because I had a lot of trouble then.”

MATH PROBLEM SOLVING. Lynn Fuchs and her colleagues (2003) assessed the value of incorporating self-regulated learning strategies into math problem-solving lessons in real classrooms. The researchers worked with 24 teachers. All of the teachers taught the same content in their third-grade classes. The teachers were randomly assigned to one of three groups. The first taught in their usual way. The second incorporated strategies to encourage problem-solving transfer—using skills and knowledge learned in the lessons to solve problems in other situations and classes. The third group added transfer and self-regulated learning strategies to their units on math problem solving. Here are a few of the transfer and self-regulated learning strategies that were taught:

- Using a key, students scored their homework and gave it to a homework collector (a peer).
- Students graphed their completion of homework on a class report.
- Students used individual thermometer graphs that were kept in folders to chart their daily scores on individual problems.
- At the beginning of each session, students inspected their previous charts and set goals to beat their previous scores.
- Students discussed with partners how they might apply problem-solving strategies outside class.
- Before some lessons, students reported to the group about how they had applied problem-solving skills outside class.

Both transfer and self-regulated learning strategies helped students learn mathematical problem solving and apply this knowledge to new problems. The addition of self-regulated learning strategies was especially effective when students were asked to solve problems that were very different from those they encountered in the lessons. Students at every achievement level as well as students with learning disabilities benefited from learning the strategies.

Technology and Self-Regulation

In the previous chapter, we saw some examples of using technology-rich environments to explore complex concepts. Over the past decade, many schools have turned to technology-mediated instruction through one-to-one laptop initiatives, online course offerings, and hybrid teaching approaches (Zheng, Warschauer, Lin, & Chang, 2016). But to learn in these rich environments, students need metacognitive and self-regulatory skills so they won’t get lost in a sea of information—and potential distraction. They need to actively evaluate the credibility and trustworthiness of information they find online. They also need motivation to stay focused in cognitively demanding, and often socially isolated, online worlds (Mayer, 2014). If the concepts they are learning are challenging and complicated, then they need some scaffolding to support their developing understandings (Azevedo, 2005; Azevedo, Johnson, Chauncey, & Graesser, 2011; Kingsley & Tancock, 2014).

For example, Melissa Duffy and Roger Azevedo (2015) studied undergraduate students who were learning about the circulatory system using a hypermedia encyclopedia. The materials available included texts, diagrams, photographs, video clips, and animated examples of how the circulatory system works. There were two different conditions. One group of students was a control group. They were asked to set two sub-goals for their learning. A second group got the same instructions, but, in addition, they were prompted to use specific self-regulated learning strategies (e.g., write a summary, take notes) and then were given feedback on the quality of their strategy. The control group got no such prompts or feedback. Those who received some scaffolding spent more time viewing relevant material and used more self-regulatory strategies. Many similar studies have shown that, much like in the face-to-face learning context, the presentation of scaffolds and prompts in the online learning context can enhance students’ self-regulation.

But the research evidence on how technology affects students’ self-regulation is still in its infancy. Some findings suggest that technologies may hinder self-monitoring and attention (Sana, Weston, & Cepeda, 2013). For example, students who used laptops to

take notes wrote more, but performed worse on a subsequent exam than students who took notes by hand (Mueller & Oppenheimer, 2014). These unexpected findings are one of the reasons why some professors (even tech experts) have decided to place limits on their students' use of digital devices in the classroom (Shirky, 2014).

How could you provide self-regulation teaching or coaching for your students as described in the study summarized above? How might you model successful self-regulated learning strategies for your students while using multimedia in your classroom or in a computer lab? How can you model responsible use (and restraint from use) of technological devices when such devices might inhibit other important forms of learning? These questions are becoming increasingly critical for today's teachers.

Another Approach to Self-Regulation: Cognitive Behavior Modification

When some psychologists were studying a behavior modification approach called *self-management*—using reinforcement and punishment to manage your own behavior—Donald Meichenbaum (1977) was having success teaching impulsive students to “talk themselves through” tasks. Meichenbaum called his method *cognitive behavior modification* (B. H. Manning & Payne, 1996). **Cognitive behavior modification** focuses on self-talk to regulate behavior.

You may remember from Chapter 2 that there is a stage in cognitive development when young children seem to guide themselves through a task using private speech (Vygotsky, 1987a). They talk to themselves, often repeating the words of a parent or teacher. In cognitive behavior modification, students are taught directly how to use this **self-instruction**. Meichenbaum (1977) outlined the steps:

1. An adult model performs a task while talking to him- or herself out loud (cognitive modeling).
2. The child performs the same task under the direction of the model's instructions (overt, external guidance).
3. The child performs the task while instructing him- or herself aloud (overt, self-guidance).
4. The child whispers the instructions to him- or herself as he/she goes through the task (faded, overt self-guidance).
5. The child performs the task while guiding his/her performance via private speech (covert self-instruction). (p. 32)

Brenda Manning and Beverly Payne (1996) list four skills that can increase student learning: listening, planning, working, and checking. How might cognitive self-instruction help students develop these skills? One possibility is to use personal booklets or class posters that prompt students to “talk to themselves” about these skills. For example, one fifth-grade class designed a set of prompts for each of the four skills and posted the prompts around the classroom. The prompts for *listening* included “Does this make sense?” “Am I getting this?” “I need to ask a question now before I forget.” “Pay attention!” “Can I do what he's saying to do?” *Planning* prompts were “Do I have everything together?” “Do I have my friends tuned out for right now?” “Let me get organized first.” “What order will I do this in?” “I know this stuff!” Posters for these and the other two skills, *working* and *checking*, are shown in Figure 11.3. Part of the power of this process lies in getting students involved in thinking about and creating their own guides and prompts. Many active reading programs encourage students to ask, “What do good readers do?” then use their answers as prompts. Having the discussion and posting the ideas makes students more self-aware and in control of their own learning.

Cognitive behavior modification as practiced by Meichenbaum and others has many more components than just teaching students to use self-instruction. Meichenbaum's methods also include dialogue and interaction between teacher and student, modeling, guided discovery, motivational strategies, feedback, careful matching of the task with the student's developmental level, and other principles of good teaching. The student is even involved in designing the program (Harris, 1990; Harris & Pressley, 1991). Given all this, it is no surprise that students seem to be able to generalize the skills developed with cognitive behavior modification to new learning situations (Harris, Graham, & Pressley, 1992).

Cognitive behavior modification Procedures based on both behavioral and cognitive learning principles for changing your own behavior by using self-talk and self-instruction.

Self-instruction Talking oneself through the steps of a task.

FIGURE 11.3

POSTERS TO REMIND STUDENTS TO “TALK THEMSELVES THROUGH” LISTENING, PLANNING, WORKING, AND CHECKING IN SCHOOL

These four posters were designed by a fifth-grade class to help them remember to use self-instruction. Some of the reminders reflect the special world of these preadolescents.

Poster 1 While Listening: 1. Does this make sense? 2. Am I getting this? 3. I need to ask a question now before I forget. 4. Pay attention. 5. Can I do what he's saying to do?	Poster 3 While Working: 1. Am I working fast enough? 2. Stop staring at my girlfriend and get back to work. 3. How much time is left? 4. Do I need to stop and start over? 5. This is hard for me, but I can manage.
Poster 2 While Planning: 1. Do I have everything together? 2. Do I have my friends tuned out for right now? 3. Let me get organized first. 4. What order will I do this in? 5. I know this stuff!	Poster 4 While Checking: 1. Did I finish everything? 2. What do I need to recheck? 3. Am I proud of this work? 4. Did I write all the words? Count them. 5. I think I finished. I organized myself. Did I daydream too much?

Today, entire school intervention programs are based on cognitive behavior modification. For example, the Coping Power Program includes training for both parents and their children, beginning in the last half of one academic year and continuing through the entire next school year. The training for students often focuses on anger and aggression. Different training sessions emphasize personal goal setting, awareness of feelings (especially anger), learning to relax and change the focus away from the angry feelings, making coping self-statements, developing organizational and study skills, seeing the perspectives of others, developing social problem-solving skills, and dealing with peer pressure by practicing how to say no (Lochman & Wells, 2003). Another similar approach is Tools for Getting Along (Daunic, Smith, Brank, & Penfield, 2006). Both programs have been effective in helping aggressive middle school students to “get along” with their classmates and teachers. In addition, in psychotherapy, tools based on cognitive behavior modification have proved to be some of the most effective ways of dealing with psychological problems such as depression.

Both the Coping Power Program and Tools for Getting Along programs include emotional self-regulation skills. We turn to this area of self-regulation next.

Emotional Self-Regulation

Social and emotional competencies and self-regulation are critical for both academic and personal development (Weissberg, Durlak, Domitrovich, & Gullotta, 2015). Individuals who effectively interpret emotions in themselves and others (e.g., anxiety, anger,

Connect and Extend to PRAXIS II®

Self-Regulation (II, A1)

Take a look at *The Merton Ethel Harris Research and Training Centre* (mehritcentre.com) for tips to help students develop the goals, metacognitive skills, and self-regulatory practices that can support a lifelong devotion to learning.

frustration, excitement), identify effective goals that incorporate those emotional signals, and eventually regulate emotion and behavior in ways that maximize successful engagement in social situations are characterized as having high *emotional intelligence* (Cassady & Boseck, 2008). School days can be filled with all kinds of emotions—some are helpful for learning, but some are not. Teachers and students need effective coping strategies to address the emotional aspects of a social or learning situation so that emotions become assets, and not barriers, to successfully achieving educational goals. These coping strategies include a broad range of skills including emotional self-regulation (Matthews, Zeidner, & Roberts, 2002). To illustrate these important strategies, the Collaborative for Academic, Social, and Emotional Learning (CASEL) lists five core social and emotional skills and competencies:

- *Self-awareness*—accurately assessing your feelings, interests, values, and strengths; maintaining a well-grounded sense of self-confidence
- *Self-management*—regulating your emotions to handle stress, control impulses, and persevere in overcoming obstacles; setting and monitoring progress toward personal and academic goals; expressing emotions appropriately
- *Social awareness*—taking the perspective of and empathizing with others; recognizing and appreciating individual and group similarities and differences; recognizing and using family, school, and community resources
- *Relationship skills*—establishing and maintaining healthy and rewarding relationships based on cooperation; resisting inappropriate social pressure; preventing, managing, and resolving interpersonal conflict; seeking help when needed
- *Responsible decision making*—making decisions based on consideration of ethical standards, safety concerns, appropriate social norms, respect for others, and likely consequences of various actions; applying decision-making skills to academic and social situations; contributing to the well-being of one's school and community (www.casel.org/)

A number of studies that followed students over several years in both the United States and Italy have found that prosocial behaviors and social competence in the early grades are related to academic achievement and popularity with peers as many as 5 years later (Elias & Schwab, 2006). Developing emotional self-regulation is especially important in the early years when students are learning how to learn in schools. For example, Carlos Valiente and his colleagues (2010) followed almost 300 students through kindergarten to assess the relations between effortful self-control, emotionality, and academic achievement. They found that students' anger, sadness, and shyness were negatively related to achievement and that self-control was positively related to achievement, particularly for students who showed lower levels of negative emotions. Clearly, helping students develop emotional self-regulation can set them on a good path for learning in school, increase their resilience, and probably can help them in social relations with their peers as well. How can teachers help?

The first way, says Daniel Goleman (2015), is by setting an example. "The teacher (and entire school staff, for that matter) ideally would model emotional and social competence for students" (p. 594). Teachers therefore need to receive emotional and social regulation instruction as part of their training. A 2017 review of U.S. teacher education programs points to the need for greater incorporation of social-emotional learning components (Schonert-Reichl, Kitil, & Hanson-Peterson, 2017). Although some colleges of education offer little in the way of social-emotional training, several outstanding programs are designed to equip preservice teachers with skills to help themselves and their students become better at regulating emotions (see, for example, The Center for Reaching and Teaching the Whole Child, <http://crtwc.org>; The Academy for Social-Emotional Learning in Schools, <http://sel.cse.edu>). The *Guidelines: Encouraging Emotional Self-Regulation* give some ideas of practices that promote emotion regulation.

GUIDELINES

Encouraging Emotional Self-Regulation

Create a climate of trust in your classroom.

Examples

1. Avoid listening to “tattle tale” stories about students.
2. Follow through with fair consequences.
3. Avoid unnecessary comparisons, and give students opportunities to improve their work.

Help students recognize and express their feelings.

Examples

1. Provide a vocabulary of emotions, and note descriptions of emotions in characters or stories.
2. Be clear and descriptive about your own emotions.
3. Encourage students to write in journals about their own feelings. Protect the privacy of these writings (see trust above).

Help students recognize emotions in others, and develop empathy and compassion.

Examples

1. For young children, “Look at Chandra’s face. How do you think she feels when you say those things?”

2. For older students, use readings, analysis of characters in literature, films, or role reversals to help them identify the emotions of others.

Provide strategies for coping with emotions.

Examples

1. Discuss or practice alternatives such as stopping to think how the other person feels, seeking help, or leaving the scene.
2. Use centering practices such as self-talk, deep breathing, or mindful movement to diffuse or prevent emotional outbursts.
3. Model strategies for students. Talk about how you handle anger, disappointment, or anxiety.

Help students recognize cultural differences in emotional expression.

Examples

1. Have students write about or discuss how they show emotions in their family.
2. Teach students to “check it out.” Ask the other people how they are feeling.

For ideas about promoting emotional competence, see casel.org

TEACHING TOWARD SELF-EFFICACY AND SELF-REGULATED LEARNING

Teacher stress is an area of considerable concern for teachers, school leaders, and researchers. In the first years of teaching, high levels of stress lead to “burnout” for teachers who are not able to develop effective coping strategies to handle the many pressures that they face (Chang, 2009).

Teacher Stress, Efficacy, and Self-Regulated Learning

Those teachers who are most effective at handling stressors in the classroom demonstrate both the high levels of teaching self-efficacy discussed earlier and a positive level of emotional self-regulation (Montgomery & Rupp, 2005; Schonert-Reichl et al., 2017). The most commonly reported sources of teacher stress are student misbehaviors, interpersonal challenges, and work-related pressure—such as meeting standards (Cano-Garcia, Padilla-Munoz, & Carrasco-Ortiz, 2005; Griffith, Steptoe, & Cropley, 1999). Teachers are more likely to maintain a healthy professional life if they can manage professional stressors such as student disruptions and pressures from parents without becoming emotionally charged, keep things in perspective, and seek support from their peers (Collie, Shapka, & Perry, 2012; Jennings & Frank, 2015; Wilkinson, 1988; Woolfolk Hoy, 2013).

One promising practice that has received recent support in research is providing teachers “mindfulness training,” which helps teachers focus attention and emotional resources on the present situation without judgment, recognizing and releasing unnecessary expectations and biases, and developing greater compassion for self and others (Roeser et al., 2013). Teachers who were randomly assigned to receive emotional skills, mindfulness stress reduction, and compassion training showed significant gains in well-being, self-efficacy,

and mindfulness, along with reduced burnout compared with teachers assigned to a control group (Jennings, Frank, Snowberg, Coccia, & Greenberg, 2013).

Designing Classrooms for Self-Regulation

STOP & THINK How are you studying right now? What goals have you set for your reading today? What is your plan for learning, and what strategies are you using right now to learn? How did you learn those strategies? •

Fortunately, a growing body of research offers guidance about how to design tasks and structure classroom interactions to support students' development of and engagement in self-regulated learning (Brown, Roediger, & McDaniel, 2014; Diamond & Ling, 2016; Perry, 1998; Stoeger & Ziegler, 2011; see Schunk & Greene, 2017). This research indicates that students develop academically effective forms of self-regulated learning and a sense of efficacy for learning when teachers involve them in *complex, meaningful tasks* that extend over *long periods of time*, much like the constructivist activities described in Chapter 10. Also, to develop self-regulated learning and self-efficacy for learning, students need to have some *control over their learning processes and products*; they need to make choices about what to work on, where, and with whom. They also need to have *control over the difficulty* of the task—how much to read or write, at what pace, and with what level of support. And because self-monitoring and self-evaluation are key to effective self-regulated learning and a sense of efficacy, teachers can help students develop self-regulated learning by involving them in *setting criteria* for evaluating their learning processes and products, and then giving them opportunities to *reflect* on and make judgments about their progress using those standards. It helps to work in *collaboration* with peers and seek feedback from them. As you saw earlier, this has been called *shared regulation*. Throughout the entire process, teachers must *co-regulate* the task by “providing just enough and just in time information and support to facilitate students' acquisition and application of” self-regulated learning (Perry & Rahim, 2011, p. 130). Let's examine each of these research-based ways to support self-regulation development more closely.

Complex Tasks

Teachers don't want to assign students tasks that are too difficult and that lead to frustration. This is especially true when students have learning struggles or disabilities. In fact, research indicates that the most motivating and academically beneficial tasks for students are those that challenge but don't overwhelm them (Mayer, 2014). Remember what you learned in Chapter 8 about extraneous cognitive load.

The term *complex* refers to the design of tasks, not their level of difficulty. From a design point of view, tasks are complex when they address multiple goals and involve large chunks of meaning—for example, projects and thematic units. Furthermore, complex tasks extend over long periods of time, engage students in a variety of cognitive and metacognitive processes, and allow for the production of a wide range of products (Perry, VandeKamp, Mercer, & Nordby, 2002). For example, a study of Egyptian pyramids might result in the production of written reports, maps, diagrams, skits, models, and even an Egyptian “museum.”

Even more important, complex tasks provide students with information about their learning progress. These tasks require them to engage in deep, elaborative thinking and problem solving. In the process, students develop and refine their cognitive and metacognitive strategies. Furthermore, succeeding at such tasks increases students' self-efficacy and intrinsic motivation (McCaslin & Good, 1996; Turner, 1997). Learning to cope with stressful situations, regulate emotions, and make adaptations is an important educational goal (Matthews, Zeidner, & Roberts, 2002). Remember from Chapter 4 that, according to Sternberg (2004), one aspect of intelligence is choosing or adapting environments so that you can succeed. Bandura (2016) would agree—one way to be an agent is to select environments that work best for you.

Control

Teachers can share control with students by giving them choices. When students have choices (e.g., about what to produce, how to produce it, where to work, whom to work with), they are more likely to anticipate a successful outcome (increased self-efficacy) and consequently increase effort and persist when difficulty arises (Turner & Paris, 1995). Also, by involving students in making decisions, teachers invite them to take responsibility for learning by planning, setting goals, monitoring progress, and evaluating outcomes (Turner, 1997). Finally, when students perceive they have control over their learning activities, they maintain higher levels of motivation to complete the task, as predicted by theories of motivation presented in Chapter 12 (Ryan & Deci, 2000). These are qualities of highly effective, self-regulating learners.

Giving students choices creates opportunities for students to adjust the level of challenge that particular tasks present (e.g., they can choose easy or more challenging reading materials, determine the nature and amount of writing in a report, supplement writing with other expressions of learning). But what if students make poor academic choices? Highly effective teachers who are high in self-regulated learning carefully consider the choices they give to students. They make sure students have the knowledge and skills they need to operate independently and make good decisions (Perry & Rahim, 2011). For example, when students are learning new skills or routines, teachers can offer choices with constraints (e.g., students must write a minimum of four sentences/paragraphs/pages, but they can choose to write more; they must demonstrate their understanding of an animal's habitat, food, and babies, but they can write, draw, or speak their knowledge).

Highly effective teachers also teach and model good decision making. For example, when students are choosing partners, teachers can ask them to consider what they need from their partner (e.g., shared interest and commitment, perhaps knowledge or skills that they need to develop). When students are making choices about how best to use their time, these teachers ask, "What can you do when you're finished? What can you do if you are waiting for my help?" Often, lists are generated and posted, so students can refer to them while they work. Finally, highly effective teachers give students feedback about the choices they make and tailor the choices they give to suit the unique characteristics of particular learners. For example, they might encourage some students to select research topics for which resources are readily available and written at a level that is accessible to the learner. Alternatively, they might encourage some students to work collaboratively versus independently to ensure they have the support and shared regulation they need to be successful.

Self-Evaluation

Evaluation practices that support self-regulated learning are nonthreatening. They are embedded in ongoing activities, emphasize process as well as products, focus on personal progress, and help students to interpret errors as opportunities for learning to occur. In these contexts, students enjoy and actually seek challenging tasks because the risk of participation—or perceived risk—is low (Paris & Ayres, 1994). Involving students in generating evaluation criteria and evaluating their own work also reduces the anxiety that often accompanies assessment by giving students a sense of control over the outcome. Students can judge their work in relation to a set of qualities both they and their teachers identify as "good" work. They can consider the effectiveness of their approaches to learning and alter their behaviors in ways that enhance it (Winne, 2011; Winne & Perry, 2000).

Classrooms that are high in self-regulated learning have both formal and informal opportunities for students to evaluate their learning. For example, one student teacher asked fourth- and fifth-grade students to submit reflection journals describing the games they designed with a partner or a small group of collaborators for a probability and statistics unit (Perry, Phillips, & Dowler, 2004). Their journals explained their contribution to the group's process and product and also described what they learned from participating. The student teacher took these reflections into account when she evaluated the games. More informally, teachers ask students, "What have you learned about yourself as a writer today?" "What do good researchers and writers do?" "What can we do that we couldn't do before?" Questions

MyLab Education

In this class, students choose work to include in their portfolios by identifying their best work and explicitly stating how each sample reflects improvement. They are involved in self-evaluation and see evidence of their growth.

like these, posed to individuals or embedded in class discussions, prompt students' metacognition, motivation, and strategic action—the components of self-regulated learning.

Collaboration

The Committee on Increasing High School Students' Engagement and Motivation to Learn (2004) concluded that when students can put their heads together, they are more receptive to challenging assignments—the very kind of complex task that develops self-regulation. The most effective uses of cooperative/collaborative relationships to support self-regulated learning are those that reflect a climate of community and shared problem solving (Perry & Drummond, 2002; Perry, VandeKamp, Mercer, & Nordby, 2002). In these contexts, teachers and students actually co-regulate one another's learning (McCaslin & Good, 1996), offering support, whether working alone, in pairs, or in small groups. This support is instrumental to individuals' development and use of metacognition, intrinsic motivation, and strategic action (e.g., sharing ideas, comparing strategies for solving problems, identifying everyone's area of expertise). Teachers who are high in self-regulated learning spend time at the start of each school year teaching routines and establishing norms of participation (e.g., how to give constructive feedback and how to interpret and respond to peers' suggestions). As you will see in Chapter 13, developing useful management and learning procedures and routines takes time at the beginning of the year, but it is time well spent. Once routines and patterns of interaction are established, students can focus on learning and teachers can attend to teaching academic skills and the curriculum.

MyLab Education [Self-Check 11.5](#)

BRINGING IT ALL TOGETHER: THEORIES OF LEARNING

How can we make sense of the diversity in perspectives on learning we have explored for the last four chapters? We have considered behavioral, cognitive, constructivist (individual and social), and social cognitive explanations of what people learn and how they learn it. Table 11.3 presents a summary of these perspectives on learning.

Rather than debating the merits of each approach in Table 11.3, consider their contributions to understanding learning and improving teaching. Don't feel that you must choose the "best" approach—there is no such thing. Chemists, biologists, and nutritionists rely on different theories to explain and improve health. Different views of learning can be used together to create productive learning environments for the diverse students you will teach. Behavioral theory helps us understand the role of cues in setting the stage for behaviors and the role of consequences and practice in encouraging or discouraging particular behaviors. But much of humans' lives and learning is more than behaviors. Language and higher-order thinking require complex information processing and memory—something the cognitive models help us understand. And what about the person as a creator and constructor of knowledge, not just a processor of information? Here, constructivist perspectives have much to offer. Social cognitive theory illustrates the powerful learning opportunities afforded through modeling and observational learning and highlights the important roles of agency and self-direction. Finally, life requires self-regulated learning, and promoting effective self-regulation skills promotes greater success in learning regardless of the operational process of learning.

I like to think of the four main learning theories in Table 11.3 as four pillars for teaching. Students must first understand and make sense of the material (constructivist); then, they must remember what they have understood (cognitive—information processing); then, they must practice and apply (behavioral) their new skills and understanding to make them more fluid and automatic—a permanent part of their repertoire. Finally, they must take charge of their own learning (social cognitive). Failure to attend to any part of the process results in lower quality learning.

MyLab Education [Self-Check 11.6](#)

TABLE 11.3 • Four Views of Learning

There are variations within each of these views of learning and overlaps as well, especially in constructivist views.

▼ SUMMARY

Social Cognitive Theory (pp. 454–457)

Distinguish between social learning and social cognitive theories. Social learning theory expanded behavioral views of reinforcement and punishment. In behavioral views, reinforcement and punishment directly affect behavior. In social learning theory, observing another person, a model, and being reinforced or punished can have similar effects on the observer's behavior. Social cognitive theory expands social learning theory to include cognitive factors such as beliefs, expectations, and perceptions of self. Current social cognitive theory is a dynamic system that explains human adaptation, learning, and motivation. The theory addresses how people develop social, emotional, cognitive, and behavioral capabilities; how people regulate their own lives; and what motivates them.

What is triadic reciprocal causality? Triadic reciprocal causality is the dynamic interplay among three kinds of influences: personal, environmental, and behavioral. Personal factors (beliefs, expectations, cognitive abilities, motivation, attitudes, and knowledge), the physical and social environment (resources, consequences of actions, other people, models and teachers, and physical settings), and behavior (individual actions, choices, and verbal statements) all influence and are influenced by each other.

Modeling: Learning by Observing Others (pp. 457–461)

What is modeling? Learning by observing others is a key element of social cognitive theory. Modeling is influenced by the developmental characteristics of the observer, the status and prestige of the model, the consequences of the model's actions as seen by the observer, the observer's expectations about performing the observed behaviors (will I be rewarded?), the links that the observers perceive between their goals and the models' behaviors (will doing what the model does get me what I want?), and the observer's self-efficacy (can I do it?).

What kinds of outcomes can observational learning encourage? Observational learning can lead to five possible outcomes: directing attention, encouraging existing behaviors, changing inhibitions, teaching new behaviors and attitudes, and arousing emotions. By directing attention, we gain insight into how others do things and what objects are involved in their actions. Encouraging or fine tuning existing behaviors can lead to the development of good habits or can make work more efficient. Observing others also has the capacity to cue us in to others' attention, which can cause us to become more or less "self-conscious" about our behavior; when others are doing something, it's easier for us to do the same. Young children in particular learn by watching and emulating others, but everyone can gain insight into how something is done well (or poorly) by observing someone else do it. Finally, observing can lead to the association of emotions with certain activities. If others are observed enjoying an activity, the observer may learn to enjoy the activity as well.

Self-Efficacy and Agency (pp. 462–467)

What is self-efficacy, and how is it different from other self-schemas? Self-efficacy is distinct from other self-schemas in that it involves judgments of capabilities specific to a particular task. Self-concept is a more global construct that contains

many perceptions about the self, including self-efficacy. Compared to self-esteem, self-efficacy is concerned with judgments of personal capabilities; self-esteem is concerned with judgments of self-worth.

What are the sources of self-efficacy?

Four sources of self-efficacy are direct experiences (of mastery or failure), vicarious experiences (performances that are modeled by someone else), social persuasion (evaluative judgments by others or specific performance feedback), and level of emotional or physiological arousal you experience as you face the task.

How does self-efficacy affect motivation? Greater self-efficacy leads to greater effort, persistence in the face of setbacks, higher goals, and finding new strategies when old ones fail. If sense of efficacy is low, however, people may avoid a task altogether or give up easily when problems arise.

What is teachers' sense of efficacy? One of the few personal characteristics of teachers related to student achievement is a teacher's sense of self-efficacy—the belief that he or she can reach even difficult students to help them learn. Teachers with a high sense of efficacy work harder, persist longer, and are less likely to experience burnout. Teachers' sense of efficacy is higher in schools where the other teachers and administrators have high expectations for students and where teachers receive help from their principals in solving instructional and management problems. Self-efficacy grows from real success with students, so any experience or training that helps you succeed in the day-to-day tasks of teaching will give you a foundation for developing a sense of efficacy in your career. There may be some benefits to a lower sense of efficacy, if this encourages teachers to pursue professional development and improvement.

Self-Regulated Learning: Skill and Will (pp. 467–478)

What factors are involved in self-regulated learning? One important goal of teaching is to prepare students for lifelong learning. To reach this goal, students must be self-regulated learners; they must have a combination of the knowledge, motivation to learn, and volition that provides the skill and will to learn independently and effectively. Knowledge includes an understanding of self, subject, task, learning strategy, and contexts for application. Motivation to learn provides the commitment and includes self-beliefs and interest. Volition is the follow-through that stays the course despite distraction. Personality characteristics such as grit, conscientiousness, and self-control are important here.

What is the self-regulated learning cycle? Zimmerman's model of self-regulated learning notes three phases: *forethought* (which includes setting goals, making plans, self-efficacy, and motivation); *performance* (which involves self-control and self-monitoring); and *reflection* (which includes self-evaluation and adaptations, leading to the forethought/planning phase again).

What are some examples of teaching students to be more self-regulating? Self-regulating learners engage in four types of activities: analyzing the task, setting goals and designing plans, engaging in learning, and adjusting their approach to

learning. Teaching students to be more self-regulating might take the form of providing opportunities to identify and analyze the task at hand. Students should ask themselves: What is the task? What is an ideal outcome of the task? Students may also benefit from goal-setting practice; they may ask: What are my short-term goals? What are my long-term goals? Learning strategies such as identifying important details and developing a big picture of material is the next step in the process. Finally, students need to reflect on whether they were successful and devise strategies for overcoming shortcomings in their self-regulation process. They may ask themselves: Where was I successful? Where do I need to improve in order to meet my goals in the future?

What is cognitive behavior modification? Cognitive behavior modification is a process in which self-talk is used to regulate behavior. Cognitive behavior modification may take many forms, including helping to keep students engaged in their learning or helping them deal effectively with anger and aggression. Some research has identified four skills that are particularly helpful self-talk strategies: listening, planning, working, and checking. Cognitive behavior modification can be used with students of all ages, but helping students engage in self-talk may require more adult assistance and guidance for younger children, or those who have not had opportunities to practice good self-regulation strategies.

What are the skills involved in emotional self-regulation? Emotionally self-regulating individuals are aware of their own emotions and the feelings of others—realizing that inner emotions can differ from outward expressions. They can talk about and express emotions in ways that are appropriate for their cultural group. They can feel empathy for others in distress and also cope with their own distressing emotions—they can handle stress. Emotional self-regulators can also employ a

variety of problem-solving and coping strategies to help them manage the personal and social emotional stimuli to promote optimal performance. These individuals know that relationships are defined in part by how emotions are communicated within the relationship. All these skills come together to produce a capacity for emotional self-regulation.

Teaching Toward Self-Efficacy and Self-Regulated Learning (pp. 479–482)

How can teachers support the development of self-efficacy and self-regulated learning? Teachers should involve students in complex meaningful tasks that extend over long periods of time. Teachers should provide students control over their learning processes and products, allowing them to make choices. They should involve students in setting criteria for evaluating their learning processes and products, and then give them opportunities to make judgments about their progress using those standards. Finally, teachers should encourage students to work collaboratively with and seek feedback from peers.

Bringing It All Together: Theories of Learning (pp. 482–483)

What is the value of the four different perspectives on learning? The behavioral, cognitive, constructivist, and social cognitive learning theories are four pillars for teaching. Students must first understand and make sense of the material (constructivist); then, they must remember what they have understood (cognitive—information processing); then, they must practice and apply (behavioral) their new skills and understanding to make them more fluid and automatic—a permanent part of their repertoire. Finally, they must take charge of their own learning (social cognitive). Failure to attend to any part of the process results in lower-quality learning.

MULTIPLE-CHOICE QUESTIONS

- Bandura identifies three forms of reinforcements that can motivate observational learning. Which of the following is NOT one of them?
 - Vicarious reinforcement
 - Self-reinforcement
 - Parental reinforcement
 - Direct reinforcement
- "I have always been among the top students in this class. I have also invested a significant amount of time on this subject. I believe I can excel in the final exam." What is this an illustration of?
 - Self-efficacy
 - Self-esteem
 - Self-concept
 - Self-regulation
- There are many ways a sense of self-efficacy can be induced. Which of the following is NOT a recognized source of self-efficacy?
 - Seeing how other people similar to you have succeeded in the same task you are pursuing.
 - Encouragement, feedback, and guidance from a trusted, prestigious source.
 - Tangible rewards, such as gifts or money, that serve to shape your perceived efficiency in a task.
 - Past successes, in the sense that you have previously completed a similar task based on your hard work and/or ability.
- At a party, Jessica was not enjoying herself because people around were playing loud music and dancing, activities that she did not particularly like. She avoided exhibiting her lack of enjoyment, as she did not want to dampen the spirits of

people who were having a good time. She understood that different people had different preferences. However, when some of her friends insisted she participate in the dancing, she yelled at them, and refused to talk to them afterwards. While Jessica demonstrated some social and emotional competencies, which of the following did she fail at?

- Self-management
- Relationship skill
- Social awareness
- Self-awareness

CONSTRUCTED-RESPONSE QUESTIONS

Case

Mr. Cheng was giving back exam sheets to his students. Jordan, who barely managed to receive a passing grade, could not control his disappointment and cried out loud, "I will never do well, NEVER! I had spent hours and hours on this subject and this is my second time obtaining such a disappointing grade. Maybe I am just not cut out for schooling."

He refused to go to school in the following days. When Mr. Cheng visited him at home, Jordan refused to talk about school. He stopped talking to his friends who expressed concerns, and started believing that no matter how hard he worked at school, he would never succeed.

- Jordan's behavior is reflective of lack of self-efficacy. Describe some of the ways in which Mr. Cheng can promote Jordan's self-efficacy.
- Jordan's emotional reaction also shows a lack of emotional competencies. Discuss some strategies that Mr. Cheng could use to improve Jordan's emotional intelligence.

▼ WHAT WOULD THEY DO?

TEACHERS' CASEBOOK: Failure to Self-Regulate

Here is how several expert teachers responded to the situation at the beginning of the chapter of the teacher with a class of disorganized students.

JANE W. CAMPBELL • Second-Grade Teacher

John P. Faber Elementary School, Dunellen, NJ

To begin the year, I teach several routines that help students to become more independent and successful. First they are introduced to a homework folder labeled with the classroom number and school name. Ownership is important, so they write their own names on the label, too. There are also designated sections for parent signatures, homework to be returned to school, and homework to be kept at home. Each day students put their things into the proper section. I check the students' success by walking through the room and looking at their folders. As different students become proficient, they become student helpers to help spot check other students as well. Organizing the students takes time, but once the routine is established, most students can successfully complete the task. As the routine is practiced and established, the students become successful and more self-reliant. Everyone is happy: the students, the parents, and the teacher.

CARLA S. HIGGINS • K-5 Literacy Coordinator

Legend Elementary School, Newark, OH

I don't make assumptions about my students' organizational skills. Instead, I explicitly teach them skills that work for our class and support future organization such as using a structured folder for class paperwork, frequent checkpoints, and an assignment calendar or agenda. I include students in planning due dates by considering what it would take to complete each assignment. For longer assignments, I ask students to help create a reasonable timeline for completing steps of the project and offer frequent checks for completion of the steps. Finally, since we live in a culture where technology drives much of our communication, I set up a Web site or e-mail reminder system to provide additional support for students and to communicate with parents to keep them involved.

MARIE HOFFMAN HURT • Eighth-Grade Foreign-Language Teacher (German and French)

Pickerington Local Schools, Pickerington, OH

Part of being a good teacher is learning how to teach the "process" of learning alongside the required content material. In the grand scheme of teaching, content-specific learning is only a small percentage of what I teach—something I didn't expect when I started my career in education. A large part of succeeding in life (and on achievement tests!), rather than just knowing how to conjugate a French verb, is knowing the habits, routines, and learning skills that students master *while* learning those French verbs. With this in mind, it is much easier

to keep the task at hand in perspective. If a teacher focuses on fundamental strategies such as organization and planning, and inextricably links these strategies to the operation of the classroom, these concepts become second nature to the students. Students are better able to absorb and learn the content-specific material because they have the tools necessary to do so.

KELLY L. HOY • Fifth Grade Humanities Teacher

Katherine Delmar Burke School, San Francisco, CA

In an elementary school classroom, organizational skills are central to alleviating stress for students, teachers, and even parents. From the desk to the binder to the backpack, somehow students' paperwork mysteriously disappears. There are ways to battle the infamous "black hole" book bag or desk. Teachers should take time at the end of each period to clearly state where the assignment should be placed, and each child can give a signal that his or her paper is in the correct place. For time-sensitive projects, having different dates in which notes, drafts, and final projects are due will help students learn time management. Students can check off that they have the correct materials in assignment logs and get a teacher's initials. Periodic "book bag checks" can help students organize their book bags for homework.

PATRICIA A. SMITH • High School Math Teacher

Earl Warren High School, San Antonio, TX

In my high school mathematics classes, I spend the first 2 months of the school year training my students in organizational skills. All of my students are given a schedule that outlines topics of discussion, assignment due dates, and quiz and test dates. I also give each of them a "scorecard" where they keep track of their own grades. This serves as a double check for me as the teacher and also provides a sense of ownership of earned grades to the students.

All my students have a three-ring binder with a plastic cover—; their schedule fits inside the plastic cover. Early in the year, I start every class with a look at the schedule and question students on assignment due dates. In addition, I collect all assignments and tests in colored folders unique to each class section. When the students walk into my classroom and see their designated color of folder on my desk, they know that something is due. Most of my quizzes are the take-home variety. I place them on a table in the back of the room, and students are responsible for locating, completing, and returning them. In fact, I put them out several days in advance and do not accept late quizzes, thereby increasing student responsibility and organization. Graded papers are also processed in the same manner, thereby perpetuating the new and orderly system and disabling the old unorganized ways.

chapter twelve

MOTIVATION IN LEARNING AND TEACHING

WHAT WOULD YOU DO? ▼

TEACHERS' CASEBOOK: Motivating Students When Resources Are Thin

It is July, and you finally have a teaching position. The district wasn't your first choice, but job openings are really tight, so you're pleased to have a job in your field. You are discovering that the teaching resources in your school are slim to none; the only materials available are some aging texts and the workbooks that go with them. Every idea you have suggested for software, learning apps, simulation games, DVDs, science project supplies, field trips, or other more active teaching materials has been met with the same response, "There's no money in the budget for that." As you look over the texts and workbooks, you wonder how the students could be anything but bored by them. To make matters worse, the texts look pretty high level for your students. But the objectives in the workbooks are important. Besides, the district curriculum requires these units. Students will be tested on them in district-wide assessments next spring.

CRITICAL THINKING

- How would you arouse student curiosity and interest about the topics and tasks in the workbooks?
- How would you establish the value of learning this material?
- How would you handle the difficulty level of the texts?
- What do you need to know about motivation to solve these problems?
- What do you need to know about your students to motivate them?

Anastasia Stepanova/Shutterstock

OVERVIEW AND OBJECTIVES

Most educators agree that motivating students is one of the critical tasks of teaching. To learn, students must be cognitively, emotionally, and behaviorally engaged in productive class activities. We begin with the question “What is motivation?” and examine many of the answers that have been proposed, including a discussion of intrinsic and extrinsic motivation. You already know quite a bit that applies to motivation based on your understanding of behavioral, cognitive, social cognitive, and sociocultural theories of learning.

Next, we consider more closely five broad factors or themes that frequently appear in discussions of motivation: needs and self-determination, goal orientations, expectancies and values, attributions and beliefs, and feelings such as interests, curiosity, flow, or anxiety. How do we put all this information together in teaching? How do we create environments, situations, and relationships that encourage motivation and engagement in learning? First, we consider how the influences on motivation come together to support motivation to learn. Then, we use the TARGET model examine how motivation is influenced by task, autonomy, recognition, grouping, evaluation and time. Finally, we discuss a number of strategies for developing motivation as a constant state in your classroom and as a permanent trait in your students.

By the time you have completed this chapter, you should be able to:

- Objective 12.1 Define motivation and contrast intrinsic and extrinsic motivation, including four kinds of extrinsic motivation.
- Objective 12.2 Explain how learners’ needs—including the needs for competence, autonomy, and relatedness—influence their motivation to learn.
- Objective 12.3 Describe the different kinds of goal orientations and examine their influences on motivation.
- Objective 12.4 Discuss how students’ beliefs about expectations for success, value of the task, and costs can influence motivation.
- Objective 12.5 Discuss how students’ beliefs and attributions about control, the nature of knowledge, mindsets, and self-worth can influence motivation.
- Objective 12.6 Describe the roles of interests, curiosity, flow, emotions, and anxiety in motivation.
- Objective 12.7 Explain how teachers can influence and encourage students’ motivation to learn.

We began our examination of motivation in the previous chapter when we explored students’ beliefs about their capabilities—their self-efficacy. I have included another chapter on motivation because students’ motivation has a direct and powerful impact on their social interactions and academic achievement in your classroom. Students with the same abilities and prior knowledge may perform quite differently, based on their motivation (Wigfield & Wentzel, 2007). So how does that work? Let’s start with a basic question. What is motivation?

Summary and Key Terms

Teachers' Casebook—Motivating Students When Resources Are Thin: What Would They Do?

WHAT IS MOTIVATION?

Motivation is usually defined as the processes that initiate, direct, and sustain behavior. Motivated students put out more effort, persist longer, learn more, and score higher on tests (Lazowski & Hulleman, 2016). Psychologists studying motivation have focused on five basic questions:

1. What choices do people make about their behavior? Why do some students, for example, focus on their homework, while others play video games?
2. How long does it take to get started? Why do some students start their homework right away, while others procrastinate?
3. What is the intensity or level of involvement in the chosen activity? Once the backpack is opened, is the student engrossed and focused or is he just going through the motions?
4. What causes someone to persist or to give up? Will a student read the entire Shakespeare assignment or just a few pages?
5. What is the person thinking and feeling while engaged in the activity? Is the student enjoying Shakespeare, feeling competent, or experiencing anxiety about an upcoming test (Anderman & Anderman, 2014; S. Graham & Weiner, 1996; Pintrich, Marx, & Boyle, 1993)?

Meeting Some Students

Many factors influence motivation and engaged learning. To get a sense of the complexity of motivation, let's step into a high school science classroom just after the teacher has given directions for a lab activity. The student profiles are adapted from Stipek (2002).

Hopeless Geraldo won't even start the assignment—as usual. He just keeps saying, “I don't understand,” or “This is too hard.” When he answers your questions correctly, he “guessed” and he “doesn't really know.” Geraldo spends most of his time staring into space; he is falling farther and farther behind.

Safe Sumet checks with you about every step—he wants to be perfect. You once gave him bonus points for doing an excellent color drawing of the apparatus, and now he produces a work of art for lab every time. But Sumet won't risk getting a B. If it isn't required or on the test, Sumet isn't interested in doing the work.

Satisfied Sophia, on the other hand, is interested in this project. In fact, she knows more than you do about it. Evidently she spends hours reading about chemistry and performing experiments. But her overall grade in your class is between B- and C because she never turns in homework. Sophia is satisfied with the C she can get on tests without even trying. *Defensive Diamond* doesn't have his lab manual—again, so he has to share with another student. Then he pretends to be working, but spends most of his time making fun of the assignment or trying to get answers from other students

when your back is turned. He is afraid to try because if he makes an effort and fails, he fears that everyone will know he is “dumb.”

Anxious Aimee is a good student in most subjects, but she freezes on science tests and “forgets” everything she knows when she has to answer questions in class. Her parents are scientists and expect her to become one too, but her prospects for this future look dim.

STOP & THINK Each of these students has problems with at least one of the five areas of motivation: (1) choices, (2) getting started, (3) intensity, (4) persistence, or (5) thoughts and feelings. Can you diagnose the problems? The answers are on page 492. •

Each student presents a different motivational challenge, yet you have to figure out how to motivate and teach the entire class. In the next few pages, we will look more closely at the meaning of motivation so we can better understand these students.

Intrinsic and Extrinsic Motivation

We all know how it feels to be motivated, to move energetically toward a goal or to work hard, even if we are not thrilled by the task. What initiates, directs, and sustains our behavior? Some psychologists have explained motivation in terms of personal *traits* or individual characteristics. Certain people, so the theory goes, are interested in cars or art, so they spend hours in garages or galleries. Other psychologists see motivation more as a *state*, a temporary situation. If, for example, you are reading this paragraph because you have a test tomorrow, you are motivated (at least for now) by the situation. Of course, the motivation we experience at any given time usually is a combination of trait and state. You may be studying because you value learning *and* because you are preparing for a test.

A classic distinction is made about amotivation, intrinsic motivation, and extrinsic motivation. **Amotivation** is a complete lack of any intent to act—no engagement at all. **Intrinsic motivation** is the natural human tendency to seek out and conquer challenges as we pursue personal interests and exercise our capabilities. When we are intrinsically motivated, we do not need incentives or punishments, because the activity itself is satisfying and rewarding (Anderman & Anderman, 2014; Deci & Ryan, 2002; Reiss, 2004). Satisfied Sophia studies chemistry outside school simply because she loves learning about chemistry; no one makes her do it.

In contrast, when we do something to earn a grade, avoid punishment, please the teacher, or for some other reason that has very little to do with the task itself, we experience **extrinsic motivation**. We are not really interested in the activity for its own sake; we care only about what it will gain us. Safe Sumet works for the grade; he has little interest in the subject itself. Extrinsic motivation has been associated with negative emotions, poor academic achievement, and maladaptive learning strategies (Corpus et al., 2009). However, extrinsic motivation also has benefits if it provides incentives as students try new things, gives them an extra push to get started, or helps them persist to complete a mundane task. Beware of either/or!

According to psychologists who adopt the intrinsic/extrinsic concept of motivation, it is impossible to tell just by looking if a behavior is intrinsically or extrinsically motivated. The essential difference between the two types of motivation is the student's *reason* for acting—whether the **locus of causality** for the action (the location of the cause) is internal or external—inside or outside the person. Students who read or practice their backstroke or paint may be reading, swimming, or painting because they freely chose the activity based on personal interests (*internal locus of causality/intrinsic motivation*), or because someone or something else outside is influencing them (*external locus of causality/extrinsic motivation*) (Reeve, 2002; Reeve & Jang, 2006a, 2006b).

As you think about your own motivation, you probably realize that the dichotomy between intrinsic and extrinsic motivation is too either/or—too all-or-nothing. Two

MyLab Education
Video Example 12.1

Students in this classroom are taking turns reading their creative writing to the class and receiving feedback to become better writers. Observe the use of extrinsic motivators as one child reads and receives feedback.

Motivation An internal state that arouses, directs, and maintains behavior.

Amotivation A complete lack of any intent to act—no engagement at all.

Intrinsic motivation Motivation associated with activities that are their own reward.

Extrinsic motivation Motivation created by external factors such as rewards and punishments.

Locus of causality The location—internal or external—of the cause of behavior.

explanations of motivation avoid either/or thinking. The first explanation is that our activities fall along a continuum from fully self-determined (intrinsic motivation) to fully determined by others (extrinsic motivation). Four types of *extrinsic* motivation are based on the level of internal drive to engage in the activity (Linnenbrink-Garcia & Patall, 2016). Starting with the *most extrinsic*, these four types are:

- *external regulation* (completely controlled by outside consequences)
- *introjected regulation* (engaging in the task to avoid guilt or negative self-perceptions)
- *identification* (participating despite lack of interest because it serves a larger goal that is personally motivating)
- *integrated regulation* (participating in a task because it is both interesting *and* has extrinsic reward value)

As an example of integrated regulation, students may freely choose to work hard on activities that they don't find particularly enjoyable because they know the activities are important in reaching a valued goal—such as spending hours studying educational psychology to become a good teacher. Those students are freely choosing to accept outside causes such as licensure requirements and then trying to get the most benefit from the requirements (Vansteenkiste, Lens, & Deci, 2006).

A second explanation that avoids either/or thinking is that intrinsic and extrinsic motivations are not two ends of a continuum. Instead, intrinsic and extrinsic tendencies are two independent possibilities, and at any given time, we can be motivated by both intrinsic and extrinsic factors (Covington & Mueller, 2001; Vansteenkiste & Mouratidis, 2016).

Connect and Extend to PRAXIS II®

Promoting Intrinsic Motivation to Learn (I, C2, 3)

For a set of practical tips, guidelines, and suggestions for boosting and maintaining motivation to learn, go to *Promoting Academic Engagement Through 21st Century Community Learning Centers: The Oregon Experience* (educationnorthwest.org/events/promoting-academic-engagement-through-21st-century-community-learning-centers-oregon).

STOP & THINK Hopeless Geraldo has trouble with getting started (2) and with a sense of despair (5); during the activity he feels defeated and helpless. Safe Sumet makes good choices (1), gets started right away (2), and persists (4). But he is not really engaged and takes little pleasure in the work (3 and 5). As long as she is following her own choices (1), Satisfied Sophia is prompt in getting started (2), engaged (3), persistent (4), and enjoys the task (5). Defensive Damond makes poor choices (1), procrastinates (2), avoids engagement (3), and gives up easily (4) because he is so concerned about how others will judge him (5). Anxious Aimee's problems have to do with what she thinks and how she feels as she works (5). Her worry and anxiety may lead her to make poor choices (1) and procrastinate (2), which only makes her more anxious at test time. •

INTRINSIC AND EXTRINSIC MOTIVATION: LESSONS FOR TEACHERS. Did you find fractions inherently interesting? Was your curiosity piqued by irregular verbs? If teachers count on intrinsic motivation to energize all their students all of the time, they will be disappointed. There are situations where incentives and external supports are necessary. Teachers must encourage and nurture intrinsic motivation, while making sure that extrinsic motivation supports learning (Anderman & Anderman, 2014; Brophy, 2003). This may become more challenging in the upper grades because both intrinsic and extrinsic motivation decline as students move up in grade levels (Linnenbrink-Garcia & Patall, 2016). To combat these trends, teachers need to know about the factors that influence motivation—and there are many. Read on.

What You Already Know About Motivation

Motivation is a vast and complicated subject encompassing many theories and explanations. Some theories were developed through work with animals in laboratories. Others are based on research with humans in situations that used games or puzzles. The work done in clinical or industrial psychology inspired additional theories as well. But you already know a bit about motivation based on the theories of learning and cognition we discussed earlier in this book. Behaviorists tend to emphasize extrinsic motivation caused by incentives, rewards, and punishment. Cognitive views stress a person's active search for meaning, understanding, and competence, and the power of the individual's

attributions and interpretations. In social cognitive theory, self-efficacy and agency are central factors in motivation. Self-efficacy is your belief that you can execute particular behaviors at a particular level in a given situation. Sociocultural views emphasize engaged participation and maintaining your identity within a community.

Even though you already have some good ideas about motivation, today there are many more specific explanations for motivation that have implications for teaching. Our examination of these explanations will be selective; otherwise we would never finish. Let's start with some more of your personal experiences with motivation.

STOP & THINK Why are you reading this chapter? Are you curious about motivation and interested in the topic? Or is there a test in your near future? Do you need this course to earn a teaching license or to graduate? Maybe you believe that you will do well in this class, and that belief keeps you working. Maybe you just got caught up in the ideas and can't put the book down. Perhaps it is some combination of these reasons. What motivates you to study motivation? •

To organize the many ideas about motivation in a way that is useful for teaching, we will examine these five broad themes or approaches. Most contemporary explanations of motivation include a discussion of needs and self-determination, goals, expectancies and values, attributions and beliefs, and finally, the emotional “hot” side of motivation—interests, curiosity, and anxiety (Murphy & Alexander, 2000). Could your answers to the *Stop & Think* questions be sorted into any of these explanations of motivation? If you don't know now, you will by the end of this chapter.

MyLab Education [Self-Check 12.1](#)

NEEDS AND SELF-DETERMINATION

Early research in psychology viewed motivation in terms of trait-like needs. Three of the main needs studied extensively in this earlier work were the needs for *achievement*, *power*, and *affiliation* (Pintrich, 2003). Abraham Maslow's influential theory emphasized a hierarchy that included all these needs and more.

Maslow's Hierarchy of Needs

Maslow (1970) suggested that humans have a **hierarchy of needs** ranging from lower-level needs for survival and safety to higher-level needs for knowledge and understanding and finally self-actualization (see Figure 12.1 on the next page). **Self-actualization** is Maslow's term for self-fulfillment, the realization of personal potential—“being all that you can be.” Each of the lower-level needs must be met before the next higher need can be addressed.

Maslow (1968) called the four lower-level needs—for survival, safety, belonging, and self-esteem—**deficiency needs**. When these needs are satisfied, the motivation for fulfilling them decreases. He labeled the three higher-level needs—cognitive needs, aesthetic needs, and finally self-actualization—**being needs**. When they are met, a person's motivation does not cease but instead increases because these being needs can never be completely filled. For example, the more successful you are in your efforts to develop as a teacher, the harder you are likely to strive for even greater improvement.

Maslow's theory has been criticized for the very obvious reason that people do not always behave as the theory would predict. Most of us move back and forth among different types of needs and may even be motivated by many needs at the same time. Some people deny themselves safety or friendship to achieve knowledge or greater self-esteem.

Criticisms aside, Maslow's theory does give us a way of looking at the whole student, whose physical, emotional, and intellectual needs are all interrelated. When children are hungry, they will have trouble focusing on academic learning. A child whose feelings of safety and sense of belonging are threatened by divorce may have little interest in learning how to divide fractions. If school is a fearful, unpredictable place where neither teachers nor students are emotionally safe, they are likely to be more concerned

MyLab Education
Video Example 12.2

Compare the notions of significance, competence, and power described in this video to the ideas of relatedness, competence, and autonomy in self-determination theory or to the concept of self-efficacy. Where are the overlaps and similarities in all these explanations of motivation?

Connect and Extend to PRAXIS II®

Maslow (I, C1)

Consider how problems with satisfying Maslow's hierarchy of needs can affect student learning. Link these ideas to direct or vicarious experiences you might have had in school.

Hierarchy of needs

Maslow's model of seven levels of human needs, from basic physiological requirements to the need for self-actualization.

Self-actualization Fulfilling one's potential.

Deficiency needs

Maslow's four lower-level needs, which must be satisfied first before higher-level needs can be addressed.

Being needs Maslow's three higher-level needs, sometimes called *growth needs*.

FIGURE 12.1

MASLOW'S HIERARCHY OF NEEDS

Maslow's four lower-level needs—for survival, then safety, followed by belonging, and then self-esteem—are called *deficiency needs*, because when these needs are satisfied, the motivation for fulfilling them decreases. He labeled the three higher-level needs—cognitive needs, then aesthetic needs, and finally self-actualization—*being needs*, because when they are met, a person's motivation does not cease.

Connect and Extend to PRAXIS II®

Self-Determination (I, C3)

Understand how self-determination can boost or diminish motivation and describe practical steps that teachers can take to establish a sense of self-determination in students.

with security and less with learning or teaching. Belonging to a social group and maintaining self-esteem within that group are important to students. If doing what the teacher says conflicts with group rules, students may choose to ignore the teacher's wishes or even defy the teacher.

Self-determination theory is a more recent approach to motivation that focuses on human needs (Deci & Ryan, 2002; Reeve, 2009).

Self-Determination: Need for Competence, Autonomy, and Relatedness

Self-determination theory suggests that we all need to feel competent and capable, to have a sense of autonomy and control over our lives, and to be connected to others in relationships. Notice that these are similar to early conceptions of basic needs for achievement (*competence*), power (*autonomy and control*), and affiliation (*relatedness*). In terms of formal definitions, **need for competence** is the individual's need to demonstrate ability or mastery over the tasks at hand. Satisfying this need results in a sense

Need for competence

The individual's need to demonstrate ability or mastery over the tasks at hand.

of accomplishment, promotes self-efficacy, and helps learners establish better learning goals for future tasks (J. Kim, Schallert, & Kim, 2010). **Need for autonomy** is central to self-determination because autonomy is the desire to have our own wishes and choices, rather than external rewards or pressures, determine our actions (Deci & Ryan, 2002; Reeve, 2009). People constantly struggle against pressure from external controls such as the rules, schedules, deadlines, orders, and limits imposed by others. Sometimes, even help is rejected so that the individual can remain in control (deCharms, 1983). The **need for relatedness** is the desire to belong and to establish close emotional bonds and attachments with others who care about us.

Because different cultures have divergent conceptions of self, some psychologists have asked whether the needs for competence, autonomy, and relatedness are universal. In a series of studies, Hyungshim Jang and her colleagues (2009) found that experiences of competence, autonomy, and relatedness were associated with satisfying learning experiences for Korean high school students, so even in a collectivistic culture, these needs may be important.

SELF-DETERMINATION IN THE CLASSROOM. Student self-determination is influenced by several factors. For instance, research in both U.S. and Korean schools demonstrated that students' motivational profiles for learning were influenced by both classroom goal structure (teachers' messages about autonomy and demonstrating competence) and the level of autonomy support offered by parents (Friedel, Cortina, Turner, & Midgley, 2007; J. Kim et al., 2010). However, the findings also suggest that for older students, the direct impact of parental attitudes and support tends to decline, whereas the influence of teachers' messages remained.

Classroom environments that support student self-determination and autonomy are associated with greater student interest and curiosity (even interest in homework assignments), sense of competence, creativity, conceptual learning, grades, school attendance and satisfaction, engagement, use of self-regulated learning strategies, psychological well-being, and preference for challenge. These relationships appear to hold from first grade through graduate school (Hafen et al., 2012; Jang, Kim, & Reeve, 2012; Moller, Deci, & Ryan, 2006; Pulfrey, Darnon, & Butera, 2013; Reeve, 2009; Shih, 2008). Autonomy may also interact with interest. In one study with college students, choice enhanced interest, sense of competence, and valuing of a reading task only when the reading passage was boring (Patall, 2013), so choice may be less important when the reading is engaging and interesting already. But in general, when students have the authority to make choices, they are more likely to believe that the work is important, even if it is not "fun." Thus, they tend to internalize educational goals and take them as their own.

In contrast to autonomy-supporting classrooms, controlling environments tend to improve performance only on rote recall tasks. When students are pressured to perform, they often seek the quickest, easiest solution. But even though controlling styles of teaching are less effective, teachers are under pressure from administrators, accountability requirements, and cultural expectations to be "in charge," and parents expect good class "discipline." In addition, students often are passive and unengaged or even defiant. Finally, some teachers equate control with efficient classroom structure or feel more comfortable with a controlling style (Reeve, 2009). Assuming you are willing to resist those pressures, how can you support student autonomy? One answer is to focus on information, not control, in your interactions with students.

INFORMATION AND CONTROL. Cognitive evaluation theory (Deci & Ryan, 2002) explains how students' experiences such as being praised or criticized, reminded of deadlines, assigned grades, given choices, or lectured about rules can influence their intrinsic motivation by affecting their sense of self-determination and competence. According to this theory, all events have two aspects: *controlling* and *informational*. If an event is highly controlling—if it pressures students to act or feel a certain

Need for autonomy The desire to have our own wishes, rather than external rewards or pressures, determine our actions.

Need for relatedness The desire to belong and to establish close emotional bonds and attachments with others who care about us.

Cognitive evaluation theory Suggests that events affect motivation through the individual's perception of the events as controlling behavior or providing information.

way—then students will experience less control, and their intrinsic motivation will be diminished. If, on the other hand, the event provides information that increases the students' sense of competence, then intrinsic motivation will increase. Of course, if the information provided makes students feel less competent, it is likely that motivation will decrease (Pintrich, 2003). Here is an example of a more *controlling* communication:

Your paper is due on Monday. Today, we are going to the school library. In the library, you will find information from books and Internet sites to use for your paper. Don't waste your time; don't goof off; make sure to get your work done. In the library, you may work by yourself or with a partner. (Reeve, 2009, p. 169)

This teacher may believe that he is supporting autonomy because he offered a *choice*. Contrast his message with the following statement that gives *information* about why the library visit is valuable:

Your paper is due on Monday. As a way of helping you write a well-researched paper, we are going to where the information is—the school library. The reason we are going to the library is to find the information you need from books and Internet sites. While there, you may be tempted to goof off, but students in the past have found that a trip to the library was a crucial part of writing an excellent paper. To help you write your best possible paper, you may work in the way you wish—by yourself or with a partner. (Reeve, 2009, p. 169)

As a teacher, what can you do to support student needs for autonomy and competence? An obvious first step is to limit your controlling messages to students because controlling language (*must, ought, have to, should . . .*) can undermine student motivation (Vansteenkiste, Simons, Lens, Sheldon, & Deci, 2004). Make sure the information you provide highlights students' growing competence by emphasizing gains made through persistence and practice and by encouraging student reflection, for example, on portfolio entries or work samples. The *Guidelines: Supporting Self-Determination and Autonomy* give some more ideas.

THE NEED FOR RELATEDNESS. Think about your best teachers over the years. What were the qualities that made them great? I bet you remember teachers who cared and forged emotional connections with you. Students who feel a sense of connection and relatedness to teachers, parents, and peers are more emotionally engaged in school and more intrinsically motivated (Furrer & Skinner, 2003; Lawson & Lawson, 2013). All students need caring teachers, but students placed at risk have an even greater need for this kind of teacher. Positive relationships with teachers increase the likelihood that students will succeed in high school and go on to college (G. Thompson, 2008; Woolfolk Hoy & Weinstein, 2006). In addition, emotional and physical problems—ranging from eating disorders to suicide—are more common among individuals who lack social relationships (Baumeister & Leary, 1995). Relatedness is similar to a sense of belonging, discussed in Chapter 3 (Osterman, 2000) as well as to Maslow's basic need for belonging described earlier in this chapter.

Needs: Lessons for Teachers

From infancy to old age, people want to be competent, connected, and in control. Students are more likely to participate in activities that help them grow more competent and less likely to engage in activities that hold the possibility of failure. This means that your students need choices and appropriately challenging tasks—not too easy, but not impossible either. They also benefit from watching their competence grow, perhaps through self-monitoring systems or portfolios. To be connected, students need to feel that people in school care about them and can be trusted to help them learn.

What else matters in motivation? Many theories include goals as key elements.

GUIDELINES

Supporting Self-Determination and Autonomy

Allow and encourage students to make choices.

Examples

1. Design several different ways to meet a learning objective (e.g., a paper, a compilation of interviews, a test, a news broadcast), and let students choose one. Encourage them to explain the reasons for their choice.
2. Appoint student committees to make suggestions about streamlining procedures such as caring for class pets or distributing equipment.
3. Provide time for independent and extended projects.
4. Allow students to choose work partners as long as they focus on the task.

Help students plan actions to accomplish self-selected goals.

Examples

1. Experiment with goal cards. Students list their short- and long-term goals and then record three or four specific actions that will move them toward the goals. Goal cards are personal—like credit cards.
2. Encourage middle and high school students to set goals in each subject area, record them in a goal book or on a thumb drive, and check progress toward the goals on a regular basis.

Hold students accountable for the consequences of their choices.

Examples

1. If students choose to work with friends and do not finish a project because too much time was spent socializing, grade the project as it deserves, and help the students see the connection between lost time and poor performance.
2. When students choose a topic that captures their imagination, discuss the connections between their

investment in the work and the quality of the products that follow.

Provide rationales for limits, rules, and constraints.

Examples

1. Explain reasons for rules.
2. Respect rules and constraints in your own behavior.

Acknowledge that negative emotions are valid reactions to teacher control.

Examples

1. Communicate that it is okay (and normal) to feel bored waiting for a turn, for example.
2. Communicate that sometimes important learning involves frustration, confusion, weariness.
3. Acknowledge students' perspective: "Yes, this problem is difficult." Or "I can understand why you might feel that way."

Use noncontrolling, positive feedback.

Examples

1. See poor performance or behavior as a problem to be solved, not a target of criticism.
2. Avoid controlling language, "should," "must," "have to."
3. Provide unexpected, spontaneous, and genuine praise.

GOALS AND GOAL ORIENTATIONS

When students strive to read a chapter or make a 4.0 GPA, they are involved in goal-directed behavior. In pursuing goals, students are generally aware of some current condition (I haven't even opened my book), some ideal condition (I have understood every page), and the discrepancy between the two. Goals motivate people to act in order to reduce the discrepancy between "where they are" and "where they want to be." Goal setting is usually effective for me. In addition to the routine tasks, such as eating lunch, which will happen without much attention, I often set goals for each day. For example, today I intend to finish this section, walk to the grocery store, order presents for my nieces from Amazon, and wash another load of clothes (I know—not too exciting). Having decided to do these things, I will feel uncomfortable if I don't complete the list.

MyLab Education Video Example 12.3

In this video, high school students work in groups to solve problems and win points in algebra class. Consider the various goal orientations that play a part in motivating students to participate and learn.

According to Locke and Latham (2002), there are four main reasons why goal setting improves performance. Goals:

1. *Direct attention* to the task at hand and away from distractions. Every time my mind wanders from this chapter, my goal of finishing the section helps snap me back.
2. *Energize effort*. The more challenging the goal, to a point, the greater the effort.
3. *Increase persistence*. When we have a clear goal, we are less likely to give up until we reach the goal: Hard goals demand effort, and tight deadlines lead to faster work.
4. *Promote the development of new knowledge* and strategies when old strategies fall short. For example, if your goal is making an A and you don't reach that goal on your first quiz, you might try a new study approach for the next quiz, such as explaining the key points to a friend.

Types of Goals and Goal Orientations

Goals that are *specific*, *elaborated*, *moderately difficult*, and *proximal* (likely to be reached in the near future) tend to enhance motivation and persistence (Anderman & Anderman, 2014; Schunk, Meece, & Pintrich, 2014).

Specific, *elaborated* goals provide clear standards for judging performance. If performance falls short, we keep going. For example, Ralph Ferretti and his colleagues (2009) gave fourth- and sixth-grade students either a general goal for writing a persuasive essay ("write a letter to a teacher about whether or not students should be given more out-of-class assignments . . .") or the general goal elaborated with specific subgoals such as:

- You need to say very clearly what your opinion or viewpoint is.
- You need to think of two or more reasons to back up your opinion.
- You need to explain why those reasons are good reasons for your opinion. (p. 580)

Students both with and without learning disabilities wrote more persuasive essays when they were given *specific subgoals*.

Moderate difficulty provides a challenge, but not an unreasonable one. Finally, goals that can be reached *fairly soon* are not likely to be pushed aside by more immediate concerns. Groups such as Alcoholics Anonymous show they are aware of the motivating value of short-term goals when they encourage their members to stop drinking "one day at a time." Also, breaking a long-term assignment into short-term steps is a way to take advantage of the motivating power of proximal goals.

STOP & THINK On a scale from 1 (Strongly Agree) to 5 (Strongly Disagree), answer these questions:

I feel really pleased in school when	
— I solve problems by working hard	— All the work is easy
— I know more than the others	— I learn something new
— I don't have to work hard	— I am the only one who gets an A
— I keep busy	— I am with my friends •
— I finish first	

FOUR ACHIEVEMENT GOAL ORIENTATIONS IN SCHOOL. Goals are specific targets. **Goal orientations** are the *reasons* we pursue goals and the *standards* we use to evaluate progress toward those goals. For example, your target might be to make an A in this course. Are you doing so in order to *master* educational psychology—to learn all about it—or to *perform*—to look good in the eyes of your friends and family? There are four main goal orientations—mastery (learning), performance (looking good), work-avoidance, and social (Dweck, 1986; Linnenbrink-Garcia & Patall, 2016; Schunk et al., 2014). In the *Stop & Think* exercise you just completed, can you tell which goal

Goal orientations Patterns of beliefs about goals related to achievement in school.

orientations are reflected in the different answers? Most of the questions were adapted from a study on students' theories about learning mathematics (Nicholls, Cobb, Wood, Yackel, & Patashnick, 1990).

The most common distinction in research on students' goals is between mastery goals (also called *task goals* or *learning goals*) and performance goals (also called *ability goals* or *ego goals*). The point of a **mastery goal** is to improve, to learn, no matter how awkward you appear. When students set mastery goals, they are more invested, especially if they feel they have choices and a sense of autonomy (Benita, Roth, & Deci, 2014; Michou et al., 2016). Students with mastery goals tend to seek challenges, persist when they encounter difficulties, and feel better about their work (Rolland, 2012). They focus on the task at hand and are not worried about how their performance “measures up” in comparison to that of others in the class. We often say that these people “get lost in their work.” In addition, they are more likely to seek appropriate help, use deeper cognitive processing strategies, apply better study strategies, and generally approach academic tasks with confidence (Anderman & Patrick, 2012; Senko et al., 2011).

Students with **performance goals** care about demonstrating their ability to others. They may be focused on getting good test scores and grades, or they may be more concerned with winning and beating other students. Students whose goal is outperforming others may do things to look smart, such as reading easy books in order to “read the most books.” Students with performance goals may act in ways that actually interfere with learning. For example, they may cheat or use short-cuts to get finished, work hard only on graded assignments, be upset and hide papers with low grades, choose tasks that are easy, avoid collaborating with other students, and be very uncomfortable with assignments that have unclear evaluation criteria (Anderman & Anderman, 2014; Senko et al., 2011).

WAIT—ARE PERFORMANCE GOALS ALWAYS BAD? Performance goals sound pretty dysfunctional, don't they? Earlier research indicated that performance goals generally were detrimental to learning, but like extrinsic motivation, a performance goal orientation may not be all bad, all of the time. In fact, some research indicates that both mastery and performance goals are associated with using active learning strategies and high self-efficacy (Midgley, Kaplan, & Middleton, 2001). For college students, pursuing performance goals has been related to higher achievement. And, as is the case with intrinsic and extrinsic motivation, students can, and often do pursue mastery and performance goals at the same time. For example, you may want to really understand educational psychology but also get a top grade in your class (Anderman & Patrick, 2012).

To account for these recent findings, educational psychologists have added an approach versus avoidance focus to the mastery/performance distinction. In other words, students may be motivated to either *approach* mastery or *avoid* misunderstanding. They may *approach* performance or *avoid* looking dumb. Table 12.1 on the next page shows examples and the effects of each kind of goal orientation. Where do you see the most problems? Do you agree that the real problems are with avoidance? Students who fear misunderstanding (mastery-avoidance) may be perfectionists—focused on getting it exactly right or afraid they will never live up to their potential. Students who try to avoid looking dumb (performance-avoidance) may adopt defensive, failure-avoiding strategies like Defensive Damond, described earlier—they cheat, pretend not to care, or make a show of “not really trying,” so they have an excuse for failure (Harackiewicz & Linnenbrink, 2005; Linnenbrink-Garcia & Patall, 2016). Research in both Eastern and Western cultures has demonstrated that failure-avoiding strategies are associated with student helplessness, truancy, disengagement from school, and lower academic achievement (De Castella, Byrne, & Covington, 2013; Huang, 2012).

Two final cautions—performance-approach goals can turn into performance-avoidance goals if students are not successful in looking smart or winning. The path might lead from performance approach (trying to win), to performance avoidance (saving face and trying not to look dumb), to learned helplessness (I give up!). So teachers are wise to avoid trying to motivate using competition and social comparisons

Mastery goal A personal intention to improve abilities and learn, no matter how performance suffers.

Performance goal A personal intention to seem competent or perform well in the eyes of others.

TABLE 12.1 • Goal Orientations

Students may have either an approach or an avoidance focus for mastery and performance goal orientations, and also may hold several orientations at once.

GOAL ORIENTATION	APPROACH FOCUS	AVOIDANCE FOCUS
Mastery	<i>Focus:</i> Mastering the task, learning, understanding <i>Standards Used:</i> Self-improvement, progress, deep understanding	<i>Focus:</i> Avoiding misunderstanding; fear of not living up to potential <i>Standards Used:</i> Just don't be wrong; Perfectionists don't make mistakes; Will I ever be what I should be?
Performance	<i>Focus:</i> Being superior, winning, being the best <i>Standards Used:</i> Normative—getting the highest grade, beating the competition, being number 1	<i>Focus:</i> Avoiding looking stupid, avoiding losing, avoiding being last <i>Standards Used:</i> Normative—don't be the worst, get the lowest grade, be the slowest, or look incompetent

Source: Based on Schunk, D. H., Meece, J., & Pintrich, P. R. (2014). *Motivation in Education: Theory, Research, and Applications* (4th ed). Pearson Education, Inc. Adapted by permission of the publisher.

(Brophy, 2005). In addition, performance-approach and performance-avoidance goals tend to be moderately correlated, so students may pursue both types of performance goals at once (Linnenbrink-Garcia et al., 2012).

SOCIAL AND WORK-AVOIDANCE GOALS. Some students don't want to learn, look smart, or avoid looking dumb. They just want to finish fast or escape work altogether, perhaps because they expect to fail or maybe because they just are not interested (Schunk, Meece, & Pintrich, 2014). John Nicholls called these students **work-avoidant learners**—they feel successful when they don't have to try hard, when the work is easy, or when they can “goof off” (Nicholls & Miller, 1984). To escape work, these students may say the assignment is too hard or too long, disrupt class, make excuses for not working, or cheat. Of course, if you avoid work using these strategies, you don't learn much and probably don't enjoy school either (King & McInerney, 2014).

A final category of goals becomes more important as students move into middle and high school—**social goals**. Adolescents try to “fit in” with their peers, but also “stand out” in some way from the crowd—a balancing act that absorbs much of their time and energy (Gray, 2014). Nonacademic activities such as athletics, dating, and “hanging out” compete with schoolwork. Some social goals support learning, but others hinder. For example, adolescents' goal of maintaining friendly relations can get in the way of learning when cooperative learning group members don't challenge wrong answers or misconceptions because they are afraid of hurting each other's feelings (Tschannen-Moran & Woolfolk Hoy, 2000). Certainly, pursuing social goals such as having fun with friends or avoiding being labeled a “nerd” can get in the way of learning. But the goal of bringing honor to your family or team by working hard or being part of a peer group that values academics certainly can support learning (Pintrich, 2003; A. Ryan, 2001; Urdan & Maehr, 1995; Zusho & Clayton, 2011). Social goals also are associated with students' emotional well-being and self-esteem. In one study, students who sought out social relationships were more likely to report positive emotional conditions such as joy, whereas students who avoided relationships reported higher levels of fear, shame, and sadness (Shim, Wang, & Cassidy, 2013).

We talk about goals in separate categories, but students can and do pursue several, often competing goals at once (Darnon, Dompnier, Gillieron, & Butera, 2010; Vansteenkiste & Mouratidis, 2016). Students have to coordinate their goals so they can make decisions about what to do and how to act. What if interest in doing homework is overtaken by interest in a videogame? What if students do not see a connection between

Work-avoidant learners

Students who don't want to learn or to look smart, but just want to avoid work.

Social goals A wide variety of needs and motives to be connected to others or part of a group.

achievement in school and success in life, particularly because discrimination prevents them from succeeding? They are not likely to set academic mastery as a goal. The need for peer relationships is basic and strong for most people, but what if social and academic goals are incompatible because peer groups do not value school? Sometimes, “fitting in” with the peer group means not achieving in school—and succeeding in the peer group is more important (Gray, 2014). Such anti-academic peer groups probably exist in every high school (Committee on Increasing High School Students’ Engagement and Motivation to Learn, 2004; Lawson & Lawson, 2013).

GOALS IN SOCIAL CONTEXT. As you know, current thinking in educational psychology puts people in context. Goal orientation theory is no exception. So, in a highly competitive classroom climate, students might be more likely to adopt performance goals. In contrast, in a supportive, learner-centered classroom, even a student with a lower sense of self-efficacy might be encouraged to aim for higher mastery goals. Goals are constructed as part of the reciprocal interactions of person, environment, and behavior described by social cognitive theory (A. Kaplan & Maehr, 2007; Zusho & Clayton, 2011).

The way students perceive their class defines the *classroom goal structure*—the goals students think are emphasized in that class (Murayama & Elliot, 2009). In one study, teachers who adopted a mastery goal orientation toward their teaching practice (e.g., become an excellent teacher) were more likely to report beliefs that all students could be successful in their classroom and to foster positive mastery goal structure. In contrast, teachers with performance-oriented goals (e.g., demonstrate they were good for the purpose of meeting state standards or job review criteria) promoted performance-oriented classroom goal structures and tended to see student ability as a fixed trait that was often outside their direct control (Shim, Cho, & Cassady, 2012). Mastery-oriented classroom goal structures matter for students. Lisa Fast and her colleagues (2010) found that fourth-through sixth-grade students had significantly higher levels of self-efficacy and mathematics achievement when they perceived their math classes as caring, challenging, and mastery oriented. So challenge, support, and a focus on learning, not looking good, seem to create a positive classroom environment.

Feedback, Goal Framing, and Goal Acceptance

In addition to having specific goals and creating supportive social relationships, three factors make goal setting in the classroom effective. The first is *feedback*. To be motivated by a discrepancy between “where you are” and “where you want to be,” you must have an accurate sense of both your current status and how far you have to go. Evidence indicates that feedback emphasizing progress is the most effective. In one study, feedback to adults emphasized either that they had accomplished 75% of the standards set or that they had fallen short of the standards by 25%. When the feedback highlighted accomplishment, the subjects’ self-confidence, analytic thinking, and performance were all enhanced (Bandura, 1997).

The second factor affecting motivation to pursue a goal is *goal framing*. When activities are linked to students’ intrinsic goals of becoming more competent, self-directed, and connected with others, then the students process information more deeply and persist longer to gain a conceptual (not superficial) understanding. Linking activities to the extrinsic goals of meeting someone else’s standards promotes rote learning—not deep understanding or persistence (Vansteenkiste, Lens, & Deci, 2006).

The third factor is *goal acceptance*. Commitment matters: The relationship between higher goals and better performance is strongest when people are committed to the goals (Locke & Latham, 2002). If students reject goals set by others or refuse to set their own goals, then their motivation will suffer. Generally, students are more willing to commit to the goals of others if the goals seem realistic, reasonably difficult, and meaningful—and if the goals are validated by connecting activities to students’ intrinsic interests (Grolnick, Gurland, Jacob, & Decourcey, 2002). So, rather than establishing the goals for the students directly, teachers can promote higher goal acceptance if the students are involved in setting goals and make an active commitment to the goal—for instance, by writing goals down and checking them off as they reach them.

Goals: Lessons for Teachers

Students are more likely to work toward goals that are clear, specific, reasonable, moderately challenging, and attainable within a relatively short period of time. If teachers focus on student performance, high grades, and competition, they may encourage students to set performance avoidance goals. This could undermine the students' ability to get deeply engaged in the task and set them on a path toward alienation from learning in school and learned helplessness (Anderman & Anderman, 2014; Brophy, 2005). Students may not yet be expert at setting their own goals or keeping these goals in mind, so encouragement and coaching are necessary. Feedback should compare students to themselves, not to others in the class—other-comparisons encourage students to avoid looking bad instead of striving to learn. If you use any reward or incentive systems, be sure the goal you set is to learn and improve in some area, not just to perform well or look smart. And be sure the goal is not too difficult. Students, like adults, are unlikely to stick with tasks or respond well to teachers who make them feel insecure or incompetent, which leads us to our next topic—the power of expectations in motivation.

MyLab Education [Self-Check 12.3](#)

EXPECTANCY-VALUE-COST EXPLANATIONS

Many influential explanations of motivation can be characterized as **expectancy × value theories**. This means that motivation is seen as the product of two main forces: the individual's *expectation* of reaching a goal and the individual's *value* of that goal. In other words, the important questions are, “If I try hard, can I succeed?” and “If I succeed, will the outcome be valuable or rewarding to me?” Notice that both expectancy and value are personal *interpretations*—maybe I really won't succeed, or perhaps the success won't be rewarding—but my perception is more powerful than reality in influencing motivation (Baron & Hulleman, 2015).

Motivation is a product of expectancy and value, because if either factor is zero, then there is no motivation to work toward the goal. For example, if I believe I have a good chance of making the basketball team (high expectation), and if making the team is very important to me (high value), then my motivation should be strong. But if either factor is zero (I believe I haven't a prayer of making the team, or I couldn't care less about playing basketball), then my motivation will be zero, too (Tollefson, 2000).

Costs

Jacqueline Eccles and Allan Wigfield added the element of *cost* to the expectancy × value equation. Values have to be considered in relation to the cost of pursuing them. How much energy/effort will be required? What could I be doing instead? What are the risks if I fail? Will I look stupid? Is the cost worth the possible benefit (Eccles, 2009; Eccles & Wigfield, 2002)? Acknowledging the cost reminds us that motivation involves not only what “pulls” us toward an activity but also what “pushes” us away because “the price is not worth it.” For example, a student might be “pushed” away from completing an assignment as an act of rebellion against the teacher—the price of cooperation is too high in terms of the student's identity as a rebel (Vansteenkiste & Mouratidis, 2016).

So the strength of our motivation in a particular situation is determined by our *expectation* that we can succeed, the *value* of that success to us, and the *cost* of pursuing the goal (Baron, & Hulleman, 2015). We talked quite a bit about expectations in Chapter 11 when we discussed social cognitive theory and self-efficacy. We will explore a related concept, *mindsets*, later in this chapter. Efficacy expectations and mindsets predict achievement in actually doing a task, but what about the value side of the equation?

Expectancy × value theories Explanations of motivation that emphasize individuals' expectations for success combined with their valuing of the goal.

Tasks Value

Value is an individual's belief about the extent to which a task or assignment is generally useful, enjoyable, or otherwise important (Conradi, Jang, & McKenna, 2014). Perceptions of value predict the choices students make about participating in a task or activity in the first place, such as whether to work hard on an assignment, enroll in advanced science classes, or join the track team (Wigfield & Eccles, 2002).

We can think of task value as having five possibilities: importance, interest, utility, pleasing others, and cost (Eccles & Wigfield, 2002; Hulleman & Barron, 2016). **Importance or attainment value** is the significance of doing well on the task; this is closely tied to the needs of the individual (the need to be well liked, athletic, masculine, etc.). For instance, if someone has a strong need to appear smart and believes that a high grade on a test proves you are smart, then the test has high attainment value for that person. A second component is **interest or intrinsic value**. This is simply the enjoyment we get from the activity itself. Some people like the experience of learning. Others enjoy the feeling of hard physical effort or the challenge of solving puzzles. Tasks also can have **utility value**; that is, they help us achieve a short-term or long-term goal such as earning a degree. Also, a task might be valuable because the activity is a way of *pleasing others*—friends, family, teachers, coaches, and so on. Finally, tasks have *costs*—negative consequences that might follow from doing the task such as not having time to do other things or looking awkward as you perform the task.

You can see from our discussion of task value that personal and environmental influences on motivation interact constantly. The task we ask students to accomplish is an aspect of the environment; it is external to the student. But the value of accomplishing the task is bound up with the internal needs, beliefs, and goals of the individual.

Lessons for Teachers

From first grade through graduate school, expectancies, values, and costs predict a number of important outcomes such as choice of activities and courses, persistence, achievement, dropping out of a major, going to graduate school, and career choices (especially for women). It appears that students must first believe that they can succeed before they will value a task, but it takes both expecting to succeed and valuing a task to improve achievement and persistence. Also, perceptions of effort costs impact decisions about leaving a major in science, engineering, mathematics, or technology or careers (Linnenbrink-Garcia & Patall, 2016). So to support motivation, teachers can do all the things described in Chapter 11 to encourage self-efficacy, but also make a powerful case for the value of their subject and help students persist in the face of difficulty, and even value the effort—the *grit*—needed to succeed.

ATTRIBUTIONS AND BELIEFS ABOUT KNOWLEDGE, ABILITY, AND SELF-WORTH

One well-known explanation of motivation begins with the assumption that we try to understand successes and failures, particularly unexpected ones—we all ask, “Why?” Students ask themselves, “Why did I flunk my midterm?” or “Why did I do so well this grading period?” They may attribute their successes and failures to ability, effort, mood, knowledge, luck, help, interest, clarity of instructions, the interference of others, unfair policies, and so on. To understand the successes and failures of others, we also make attributions—that the others are smart or lucky or work hard, for example. **Attribution theories** of motivation describe how the individual's explanations, justifications, and excuses influence motivation (Anderman & Anderman, 2014).

Bernard Weiner is one of the main educational psychologists responsible for relating attribution theory to school learning (Weiner, 2000, 2010, 2011). According to Weiner,

Attribution Theory (I, C1)

Go to the *Encyclopedia of Psychology* Do a web search for “attribution theory” to learn more about using principles derived from this theory to boost intrinsic motivation to learn.

Value An individual's belief about the extent to which a task or assignment is generally useful, enjoyable, or otherwise important.

Importance or attainment value The importance of doing well on a task; how success on the task meets personal needs.

Interest or intrinsic value The enjoyment a person gets from a task.

Utility value The contribution of a task to meeting one's goals.

Attribution theories Descriptions of how individuals' explanations, justifications, and excuses influence their motivation and behavior.

most of the attributed causes for successes or failures can be characterized in terms of three dimensions:

1. *Locus* (location of the cause—internal or external to the person). For example, attributing a great piano performance to your musical talent or hard work are internal attributions. Explaining that the performance is based on coaching from a great teacher is an external attribution.
2. *Stability* (whether the cause of the event is the same across time and in different situations). For example, talent is stable, but effort can change.
3. *Controllability* (whether the person can control the cause). For example, effort and finding a great teacher are controllable, but innate musical talent is not.

Every cause for success or failure can be categorized on these three dimensions. For instance, luck is external (locus), unstable (stability), and uncontrollable (controllability). In attribution theory, ability is usually considered stable and uncontrollable, but as we will soon see, intelligence can be viewed as unstable and controllable. Weiner's locus and controllability dimensions are closely related to Deci's concept of locus of causality.

Weiner believes that these three dimensions have important implications for motivation because they affect expectancy and value. The *stability* dimension, for example, seems to be closely related to expectations about the future. If students attribute their failure to stable factors such as the difficulty of the subject or an unfair teacher, they will expect to keep failing in that subject or with that teacher. But if they attribute the outcome to unstable factors such as mood or luck, they can hope for better outcomes next time. The *internal/external locus* seems to be closely related to feelings of self-esteem. If success or failure is attributed to internal factors, success will lead to pride and increased motivation, whereas failure will diminish self-esteem. The *controllability* dimension is related to emotions such as anger, pity, gratitude, or shame. If we feel responsible for our failures, we may feel guilt; if we feel responsible for successes, we may feel proud. Failing at a task we cannot control can lead to shame or anger (Weiner, 2010, 2011).

Feeling in control of your own learning seems to be related to choosing more difficult academic tasks, putting out more effort, using better strategies, and persisting longer in school work (Anderman & Anderman, 2014; Weiner, 1994a, 1994b). Factors such as continuing discrimination against women, people of color, and individuals with special needs can affect these individuals' perceptions of their ability to control their lives (van Laar, 2000).

Attributions in the Classroom

People with a strong sense of **self-efficacy** (see Chapter 11) for a given task ("I'm good at math") tend to attribute their failures to lack of effort ("I should have double-checked my work"), misunderstanding directions, or just not studying enough. These are internal, controllable attributions. As a consequence, students with high self-efficacy usually focus on strategies for succeeding next time. This response often leads to achievement, pride, and a greater feeling of control. But people with a low sense of self-efficacy ("I'm terrible at math") tend to attribute their failures to lack of ability ("I'm just dumb"). These tendencies are apparent across age levels, cultural groups, and academic topics (Hsieh & Kang, 2010).

The greatest motivational problems arise when students attribute failures to stable, uncontrollable causes. Such students may seem resigned to failure, depressed, helpless—what we generally call "unmotivated" (Weiner, 2000, 2010). These students respond to failure by focusing even more on their own inadequacy; their attitudes toward schoolwork may deteriorate even further. Apathy is a logical reaction to failure if students believe the causes are stable, unlikely to change, and beyond their control anyway. In addition, students who view their failures in this light are less likely to seek help; they believe nothing and no one can help, so they conceal their needs for assistance. This creates a downward spiral of failure and concealment—"the motivationally 'poor' children, by concealing their difficulties, become 'poorer'" (Marchland & Skinner, 2007).

Self-efficacy A person's sense of being able to deal effectively with a particular task. Beliefs about personal competence in a particular situation.

Students with high levels of test anxiety and multiple poor performances on tests report a higher degree of helplessness as well. After taking a test, these students blame their poor performance on test anxiety that “got in the way” of doing their best (Cassady, 2004). This leads to a spiral of reduced effort in future studying because they believe improved performance is outside their control—and naturally, their performance continues to suffer (Schunk, Meece, & Pintrich, 2014).

Teacher Attributions Trigger Student Attributions

When a teacher attributes student failure to forces beyond the student’s control, the teacher tends to respond with sympathy and avoid giving punishments. If, however, the failures are attributed to a controllable factor such as lack of effort, the teacher’s response is more likely to be irritation or anger, and reprimands may follow. These tendencies seem to be consistent across time and cultures (Weiner, 1986, 2000, 2011).

What do students make of these reactions from their teachers? Sandra Graham (1991, 1996) gives some surprising answers. Evidence indicates that when teachers respond to students’ mistakes with pity, praise for a “good try,” or unsolicited help, the students are more likely to attribute their own failure to an uncontrollable cause—usually lack of ability. Does this mean that teachers should be critical and withhold help? Of course not! But it is a reminder that over-solicitous help can give unintended messages. Graham (1991) suggests that many minority group students could be the victims of well-meaning pity from teachers. Seeing the very real problems that the students face, teachers may “ease up” on requirements so the students will “experience success.” But an indirect communication may accompany the pity, praise, and extra help: “You don’t have the ability to do this, so I will overlook your failure.” This kind of feedback, even if well intended, can be a subtle form of racism.

Teachers can also positively impact student’s attributions, with benefits to both achievement and motivation. In work with gifted girls in a physics class, when teachers encouraged the girls to attribute improved performance to personal effort and abilities, the girls were more engaged, and their achievement improved (Ziegler & Heller, 2000). Finally, helping lower performing students attribute achievement to effort instead of ability has improved their course grades and test performance (Hulleman & Barron, 2016).

Thus far, we have talked about needs, goals, expectancies, values, costs, and attributions, but there is another factor that must be considered in explaining motivation. What do students believe about learning, abilities, and themselves? Let’s start with a basic question: What do students believe about knowing?

Beliefs About Knowing: Epistemological Beliefs

What students believe about knowledge and learning (their **epistemological beliefs**) will influence their motivation and the kinds of strategies that they use.

PUT YOURSELF IN THEIR PLACE Predict how fourth and sixth graders would answer these questions taken from C. K. Chan and Sachs (2001).

1. Which of the following is the most important thing in learning math? (a) remember what the teacher has taught you, (b) practice lots of problems, (c) understand the problems you work on.
2. Which of the following is the most important thing to do in learning science? (a) faithfully do the work the teacher tells you, (b) try to see how the explanation makes sense, (c) try to remember everything you are supposed to know.
3. If you wanted to know everything there is to know about something, say, animals, how long would you have to study it? (a) less than a year if you study hard, (b) about 1 or 2 years, (c) forever.
4. What happens when you learn more and more about something? (a) the questions get more and more complex, (b) the questions get easier and easier, (c) the questions all get answered.

How about you? How would you answer these questions? •

Epistemological beliefs
Beliefs about the structure, stability, and certainty of knowledge, and how knowledge is best learned.

Using questions like those in *Put Yourself in Their Place*, researchers have identified several dimensions of epistemological beliefs (C. K. Chan & Sachs, 2001; Schommer, 1997; Schommer-Aikins, 2002; Schraw & Olafson, 2002). For example:

- *Structure of Knowledge*: Is knowledge in a field a simple set of facts or a complex structure of concepts and relationships?
- *Stability/Certainty of Knowledge*: Is knowledge fixed, or does it evolve over time?
- *Ability to Learn*: Is the ability to learn fixed (based on innate ability) or changeable?
